FCC-ee feasibility study

FCC-ee Energy Calibration and Polarization

Recent CDF: m_W (MeV)= 80'433.5 ± 6.4 _{stat} ± 6.9_{syst} (10⁻⁴ precision)

-- « could hint at new physics » and <u>surely</u> created a buzz!

-- precision measurements as broad exploration of new physics in quantum corrections, or mixing (SUSY, Heavy neutrinos, etc..)

(-- questions because inconsistent with previous measurements)

CDF measurement is remarkable in two ways:1. (after 10 years of work)systematic errors similar to statistical precision

2. relies for the precise calibration on J/ ψ , Υ , Z masses all measured in e+e- colliders...

using resonant depolarization!

Resonant depolarization is the cornerstone of the precision programme of FCC-ee

~40 times more precise than CDF

→ Improvement by factor 10-1000 on a long list of precision measurements. e.g. W mass down to ± 250 keV, Z mass and width ± 4 keV, $\sin^2\theta_w^{\text{eff}} \pm 2.10^{-6}$ etc.

 \rightarrow explore new physics at 10-100 TeV scale, or 10⁻⁵ mixing with known particles.

factor 500 more precise than LEP

based on spin precession frequency measurement

1. Establish e-, e+ beam polarization on machine in 'collision mode'

- -- constraints on machine set-up, energy, (wigglers), corrections etc...
- -- measure beam polarization (polarimeters)

2. measure spin precession frequency

- -- resonant depolarization
- -- or/and measure spin precession
- 3. relation between spin precession and average beam energy
- 4. relation between average e+e- beam energies and beam energies at IP
 - -- Synchrotron radiation losses
 - -- beamstrahlung losses
 - -- measurement of center-of-mass energy spread

5. relation between beam energies and $\rm E_{\rm cm}$

Beam Polarization can provide two main ingredients to Physics Measurements

- 1. Transverse beam polarization provides beam energy calibration by resonant depolarization
 - \rightarrow low level of polarization is required (~10% is sufficient)
 - \rightarrow at Z & W pair threshold comes naturally $\sigma_E \propto E^2/\sqrt{\rho}$
 - → at Z use of asymmetric wigglers at beginning of fills since polarization time is otherwise very long (250h → ~1h)
 - \rightarrow should be used also at ee \rightarrow H(126)
 - → use 'single' non-colliding bunches and calibrate continuously during physics fills to avoid issues encountered at LEP
 - ightarrow Compton polarimeter for both e+ and e-
 - \rightarrow should calibrate at energies corresponding to half-integer spin tune
 - \rightarrow must be complemented by analysis of «average E_beam-to-E_CM» relationship

For beam energies higher than ~90 GeV can use ee \rightarrow Z γ or ee \rightarrow WW events to calibrate E_{CM} at ±1-5 MeV level: m_H (5 MeV) and m_{top} (20 MeV) measts

6/29/2022

6

E [MeV]

Beam Polarization can provide two main ingredients to Physics Measurements

Here-system
 Hust compare with natural e+e- polarization due to chiral coverinal Polarization or with final state polarization analysis for CC weak decay on state and polarized) (tau ar.
 Physics case for Z peak is very well studied and more with final state polarization analysis for CC weak decay on state and polarized) (tau ar.
 A_{LR} = A_e, A_{FB}^{Pol}(f) etc... (CERN Y.R. & done with final state polarization measures that can be controlled e+ and e- polarization at high statistics A_{FB}^{Pol} = A on physics unit of A_{LR} (Tenchini)
 enhance Higgs cross service for an state analysis does as well (Janot arXiv:1503.01325) enhance here with attoin level and often both e- and e+ polarization
 require could be with attoin level and often both e- and e+ polarization
 As far as we be doing If loss of luminosity is too high
 As far cannot nigh level of polarization in high luminosity collistication

Table 3: Center-of-mass energies for the proposed Z scan. The points noted A and B are half integer spin tune points with energies closest to the requested energies.

Scan point	Centre-of-mass Energy	Beam Energy	Spin tune
$E_{CM}^{-} A$	87.69	43.85	99.5
E_{CM}^{-} Request	87.9	43.95	99.7
$E_{\rm CM}^-$ B	88.57	44.28	100.5
E_{CM}^0	91.21	45.61	103.5
$E_{CM}^+ A$	93.86	46.93	106.5
E_{CM}^+ Request	94.3	47.15	107.0
$E_{CM}^+ B$	94.74	47.37	107.5

centre-of-mass energy errors:

$$\frac{\Delta m_{Z}}{m_{Z}} = \left\{ \frac{\Delta \sqrt{s}}{\sqrt{s}} \right\}_{\text{abs}} \oplus \left\{ \frac{\Delta(\sqrt{s_{\pm}} + \sqrt{s_{-}})}{\sqrt{s_{\pm}} + \sqrt{s_{-}}} \right\}_{\text{ptp-syst}} \oplus \left\{ \frac{\Delta \sqrt{s_{\pm}^{i}}}{\sqrt{s_{\pm}^{i} N_{\pm}^{i}}} \right\}_{\text{sampling}},$$

$$\frac{\Delta \Gamma_{Z}}{\Gamma_{Z}} = \left\{ \frac{\Delta \sqrt{s}}{\sqrt{s}} \right\}_{\text{abs}} \oplus \left\{ \frac{\Delta(\sqrt{s_{\pm}} - \sqrt{s_{-}})}{\sqrt{s_{\pm}} - \sqrt{s_{-}}} \right\}_{\text{ptp-syst}} \oplus \left\{ \frac{\Delta \sqrt{s_{\pm}^{i}}}{\sqrt{s_{\pm}^{i} N_{\pm}^{i}}} \right\}_{\text{sampling}},$$

$$\Delta A_{\text{FB}}^{\mu\mu}(\text{pole}) = \frac{\partial A_{\text{FB}}^{\mu\mu}}{\partial \sqrt{s}} \left\{ \Delta(\sqrt{s_{0}} - 0.5(\sqrt{s_{\pm}} + \sqrt{s_{-}})) \right\}_{\text{ptp-syst}} \oplus \left\{ \frac{\partial A_{\text{FB}}^{\mu\mu}}{\partial \sqrt{s}} \left\{ \frac{\Delta \sqrt{s_{0,\pm}^{i}}}{\sqrt{N_{0,\pm}^{i}}} \right\}_{\text{sampling}},$$

$$(3.1)$$

$$\frac{\Delta \alpha_{\text{QED}}(m_{Z}^{2})}{\alpha_{\text{QED}}(m_{Z}^{2})} = \left\{ \frac{\Delta \sqrt{s}}{\sqrt{s}} \right\}_{\text{abs}} \oplus \left\{ \frac{\Delta(\sqrt{s_{\pm}} - \sqrt{s_{-}})}{\sqrt{s_{\pm}} - \sqrt{s_{-}}} \right\}_{\text{ptp-syst}} \oplus \left\{ \frac{\Delta \sqrt{s_{\pm}^{i}}}{\sqrt{s_{\pm}^{i} N_{\pm}^{i}}} \right\}_{\text{sampling}},$$

with $\frac{\partial A_{\rm FB}^{\mu\mu}}{\partial \sqrt{s}} \simeq 0.09/{\rm GeV}.$

Three categories:

- Absolute dominate for Z and W mass
- **ptp** Point-to-point dominate for $\Gamma_z \& A_{FB}^{\mu\mu}$ (peak and off-peak)
- Due to sampling turns out to be negligible for 1 meast /(15 min= 1000s) \rightarrow 10⁴ measts

Table 4. Calculated uncertainties on the quantities most affected by the centre-of-mass energy uncertainties, under the initial systematic assumptions.

	statistics	$\Delta \sqrt{s}_{\rm abs}$	$\Delta \sqrt{s}_{\rm syst-ptp}$	calib. stats.	$\sigma_{\sqrt{s}}$

Polarization and Centre-of-mass Energy Calibration at FCC-ee, arXiv:1909.12245

Table 15: Calculated uncertainties on the quantities most affected by the center-or-mass energy uncertainties, under the final systematic assumptions.

Quantity	statis	tics	$\Delta E_{\rm CMabs}$	$\Delta E_{\rm CMSyst-ptp}$	calib. stats.	σE_{CM}	stat/nresent
			100 keV	40 keV	$200 \text{ keV}/\sqrt{(N^i)}$	$(84) \pm 0.05$ MeV	staty present
m _Z (keV)	4		100	28	1	-	500
$\Gamma_{\rm Z}$ (keV)	4		2.5	22	1	10	400
$sin^2 \theta_W^{\text{eff}} \times 10^6 \text{ from } A_{FB}^{\mu\mu}$	2		_	2.4	0.1	-	75
$\frac{\Delta \alpha_{QED}(M_Z)}{\alpha_{QED}(M_Z)} \times 10^5$	3		0.1	0.9	_	0.05	15 (qualitiative!)
m _W (MeV)	0.2	250	0.3	00			40

Next challenges for the feasibility study:

- -- Ascertain the above with integrated simulations (simulation of polarization and depolarization on real machine)
- -- Match systematic errors with statistics.

most relevant targets : the point-to-point systematics, improve the WW energy

- these are effects that would lead to a deviation from relation between
 - -- the spin tune as measured by resonant depolarization
 - -- and the center-of-mass energy.
- -- examples: 1. interference between depolarizing resonances and the induced depolarizing resonance

because the spin tune varies with energy.

2. effects due to collision offsets folded by opposite sign dispersion

- -- designevaluate performance and cost the polarimeter at conceptual level
- -- finalize implementation in the realistic machine, study operational aspects

Requirements from physics (feasibility study): match statistical precision!

- 1. Center-of-mass energy determination with precision of $<= \pm 4$ keV around the Z peak
- 2. Center-of-mass energy determination with precision of <= 200 keV at W pair threshold
- 3. For the Z peak-cross-section and width, require energy spread uncertainty $\Delta \sigma_{\rm E} / \sigma_{\rm E} = 0.1\%$

NB: at 2.3 10^{36} /cm²/s/IP : full LEP statistics $10^{6} \mu \mu \& 2.10^{7} qq$ in 6 minutes in each expt

- -- use resonant depolarization as main measuring method
- -- use pilot bunches to calibrate during physics data taking: 100 calibrations per day each 10⁻⁶ rel
- -- long lifetime at Z requires the use of wigglers at beginning of fills
- → take data at points where self polarization is expected

$$v_{s} = \frac{g-2}{2} \frac{E_{b}}{m_{e}} = \frac{E_{b}}{0.4406486(1)} \approx N + (0.5 \pm 0.1) \qquad \mathbf{E}_{CM} = (N + (0.5 \pm 0.1)) \times 0.8812972 \text{ GeV}$$

Given the Z and W widths of 2 GeV, this is easy to accommodate with little loss of statistics. <u>It might be more difficult for the Higgs 125.09+-0.2 corresponds to $v_s = 141.94+-022$ </u>

Simulations of self-polarization level with SITROS

Some results of coupling/dispersion correction

Oide optics with Q_x=0.1, Q_y=0.2, Q_s=0.05

• δy^Q_{rms} =200 μ m (including doublets)

E. Gianfelice

- 250 μ rad quadrupole roll angle (including doublets)
- 1086 BPMs w/o errors
- orbit corrected with 1086 CVs down to $y_{rms}{=}0.05$ mm
- $\bullet\$ coupling/dispersion correction with 289 skew quadrupoles

 orbit and emittance corrections needed for the FCC-ee luminosity seem sufficient to ensure useful levels of polarization
 HOWEVER: same simulation does not produce luminosity and polarization,
 → effect of simultaneous optimization could not be simulated

Oide optics with $Q_x=0.1$, $Q_y=0.2$, $Q_s=0.05$

Excellent level of polarization at the Z (even with wigglers) and sufficient at the W $\sigma_E \propto E^2/\rho$

recent progress: Implementation of FCC-ee machine lattice in BMAD -- Cornell code incl. imprefections luminosity and polarization (+ resonant depolarization) implementation in MADx in progress (T. Persson, CERN)

- Resonances enhanced with increasing closed orbit
- More misalignments can reduce maximum polarization \rightarrow orbit corrections essential

100 microrad orbit kick gets compensated by the pi bump but generates a lasting **25 mrad spin kick**

the pi bump generates a spin component rotation of the spin in the x-z direction. The largest rotation is created by the QD quadrupole (focus in vertical plane)

B

RESONANT DEPOLARIZATION

= 103.5 at the Z peak

Once the beams are polarized, an RF kicker at the spin precession frequencv will provoke a spin flip and complete depolarization Simulation of FCC-ee by I. Kopp:

Figure 39. Simulation of a frequency sweep with the depolarizer on the Z pole showing a very sharp depolarization at the exact spin tune value.

long sweep works well at the Z. Several depolarizations needed: eliminate Qs side band and 0.5 ambiguity Less well at the W: the Qs side bands are much more excited because of energy spread, need iterations with smaller and smaller sweeps – work in progress. see *I. Koop* presentations at FCC weeks.

FCC Recent progress: resonant depolarization a the WW threshold (should allow 100 keV or better Ecm calibbration) Depolarization Process

• Resonant depolarization allows to determine spin tune and thus energy

At W Qs too large, stepwise depolariozation required

FT of spin coherent spin motion gives spin tune

FCC From beam energy to E_{CM} $\sqrt{s} = 2\sqrt{E_{b}^{+}E_{b}^{-}}\cos \alpha/2, \approx E_{b}^{+} + E_{b}^{-}$

Energy gain (RF) = losses in the storage ring Synchrotron radiation (SR) beamstrahlung (BS)

 $\begin{array}{ll} \Delta_{\text{RF}} = 2 \Delta_{\text{SRi}} + 2 \Delta_{\text{SRe}} + 2 \Delta_{\text{BS}} \\ \text{at the Z (O of mag.):} \\ \Delta_{\text{SR}} = 2 \Delta_{\text{SRi}} + 2 \Delta_{\text{SRe}} & = 36 \text{ MeV} \\ \Delta_{\text{SRe}} - \Delta_{\text{SRi}} \approx \alpha / 2 \pi \Delta_{\text{SR}} = 0.17 \text{ MeV} \\ \Delta_{\text{BS}} & = 0 \text{ up to } 0.62 \text{ MeV} \end{array}$

the average energies E_0 around the ring are determined by the magnetic fields \rightarrow same for colliding or non-colliding beams -- measured by resonant depolarization $-- can_2be$ different for e^+ and e^- Alam blondel Physics at the FCCs

$\leftarrow E_0$ at half RF

single RF system → E⁺ + E⁻ constant if e+, e- energy losses are the same (mod higher order corrections) cross-checks: E⁺ - E⁻ (boost of CM), + measured Z masses!

IP2

Resonant depolarization frequency vs average beam energy?

(just because particles have to stay in the ring) effect of energy losses and gains cancel...

IF there is only one RF section for both e+ and e-

Jacqueline Keintzel

ightarrow a strong requirement for the Z, W (and ee ightarrow H) machines

The boosts can be verified with great precision, using muon pairs in the experiments, (\pm 40 keV in 5 minutes). Also, the energy spread can be measured

FCC FCC-ee Beam Polarization and Energy Calibration

3. From spin tune measurement to center-of-mass determination $v_s = \frac{g-2}{2} \frac{E_b}{m_c} = \frac{E_b}{0.4406486(1)}$

3.1 Synchrotron Radiation energy loss (9 MeV @Z in 4 'arcs') calculable to < permil accuracy 3.3 Beamstrahlung energy loss (0.62 MeV per beam at Z pole), compensated by RF (Shatilov) 3.4 layout of accelerator with IPs between two arcs well separated from single RF section

3.5 E_{b}^{+} vs E_{b}^{-} asymmetries and energy spread can be measured/monitored in expt:

 $e+e- \rightarrow \mu + \mu$ - longitudinal momentum shift and spread (Janot)

Hardware requirements: wigglers

Given the long polarization time at Z, wigglers will be necessary. An agreement was reached on a set of **8 wiggler units per beam**

Polarization wigglers

FCC

8 units per beam, as specified by *Eliana Gianfelice* B+=0.7 T L+ = 43cm L-/L+ = B+/B- = 6 at Eb= 45.6 GeV and B+= 0.67 T => P=10% in 1.8H σ_{Fh} = 60 MeV E_{crit}=902 keV

placed e.g. in dispersion-free straight section H and/or F

First single pole magnetic concept, keeps some of the ideas of the LEP design, in particular the "floating" poles

polarimeters

2 Polarimeters, for e+ and e- Use of both electron and photons recoil \rightarrow measurement of 3D beam polarization Backscattered Compton γ +e $\rightarrow \gamma$ + e 532 nm (2.33 eV) laser; detection of photon and electron. Change upon flip of laser circular polarization \rightarrow beam Polarization ± 0.01 per second End point of recoil electron \rightarrow beam energy monitoring ± 4 MeV per second (Muchnoi, Aurelien Martens)

polarimeter-spectrometer situated 100m from end of dipole.

Using the dispersion suppressor dipole with a lever-arm of **100m** from the end of the dipole, one finds

-- minimum compton scattering energy at 45.6 GeV is 17.354 GeV

-- distance from photon recoil to Emin electron is 0.628m

measurement of recoil e and

Munchnoi

O FCC

Compton Polarimeter: Rates

- Laser wavelength $\lambda = 532$ nm.
- Waist size $\sigma_0 = 0.250$ mm. Rayleigh length $z_R = 148$ cm.
- Far field divergence $\theta = 0.169 \text{ mrad}$
- Interaction angle $\alpha = 1.000 \text{ mrad}$
- Compton cross section correction 0.5
- Pulse energy: $E_L = 1$ [mJ]; $\tau_L = 5$ [ns] (sigma)
- Pulse power: $P_L = 80 \text{ [kW]}$
- Ratio of angles $R_a = 5.905249$
- Ratio of lengths $R_l = 0.984208$

•
$$P_L/P_c = 1.1 \cdot 10^{-6}$$

- "efficiency" = 0.13
- Scattering probability $W \simeq 7 \cdot 10^{-8}$
- With 10^{10} electrons and 3 kHz rep. rate: $\dot{N}_{\gamma}\simeq 2\cdot 10^6$

O FCC

- This is not-so trivial in FCC-ee! 16700 bunches circulate time-between-bunches = 19ns, depolarize one-and-only-one of them.
- Kicker must have fast (<9ns) rise.
- The LHC TF system works essentially on a bunch by bunch basis for 25ns. They would provide a transverse kick of up to ~20 mrad at the Z peak with ~10 MHz bandwidth. This is 10x more than what we may need-
- ➔ a priori OK !

Energy calibration WG / J. Wenninger

Depolarization

LHC transverse feedback system

- Four kickers per beam, per plane, located in RF zone (UX451) at point 4
 - Electrostatic kicker, length 1.5 m.
 - Providing a kick of ~2 μrad @ 450 GeV (all 4 units combined).
 - Useful bandwidth ~1 kHz 20 MHz.

FCC From spin tune to beam energy--

The spin tune may not be en exact measurement of the average of the beam energy along the magnetic trajectory of particles. Additional spin rotations may bias the issue. *Anton Bogomyagkov* and *Eliana Gianfelice* have made many estimates.

synchrotron oscillations	$\Delta E/E$	-2 10 ⁻¹⁴
Energy dependent momentum compaction	$\Delta E/E$	10 ⁻⁷
Solenoid compensation		2 10 ⁻¹¹
Horizontal betatron oscillations	$\Delta E/E$	2.5 10 ⁻⁷
Horizontal correctors*)	$\Delta E/E$	2.5 10 ⁻⁷
Vertical betatron oscillations **)	$\Delta E/E$	2.5 10 ⁻⁷

invariant mass shift due to beam potential		4 10 ⁻¹⁰

*) 2.5 10⁻⁶ if horizontal orbit change by >0.8mm between calibrations is unnoticed or if quadrupole stability worse than 5 microns over that time. consider that 0.2 mm orbit will be noticed **) 2.5 10⁻⁶ for vertical excursion of 1mm. Consider orbit can be corrected better than 0.3 mm.

 $\Delta y (\mu m)$

7.2 Dispersion at the IP

For beams colliding with an offset at the IP, the CM energy spread and shift are affected by the local dispersion at the IP. For a total IP separation of the beams of $2u_0$ the expressions for the CM energy shift and spread are [72]

$$\Delta\sqrt{s} = -2u_0 \frac{\sigma_E^2(D_{u1} - D_{u2})}{E_0(\sigma_{B1}^2 + \sigma_{B2}^2)}$$
(90)

$$\sigma_{\sqrt{s}}^2 = \sigma_E^2 \left[\frac{\sigma_e^2 (D_{u1} + D_{u2})^2 + 4\sigma_u^2}{\sigma_{B1}^2 + \sigma_{B2}^2} \right]$$
(91)

 D_{u1} and D_{u2} represent the dispersion at the IP for the two beams labelled by 1 and 2. σ_E is the beam energy spread assumed here to be equal for both beams and $\sigma_e = \sigma_E/E$ is the relative energy spread. σ_{Bi} is the total transverse size of beam (i) at the IP,

$$\sigma_{Bi}^2 = \sigma_u^2 + (D_{ui}\sigma_e)^2 \tag{92}$$

with σ_u the betatronic component of the beam size.

If the beam sizes at the IP are dominated by the betatronic component which is rather likely, the energy shift simplifies to

$$\Delta \sqrt{s} = -u_0 \frac{\sigma_E^2 \Delta D^*}{E_0 \sigma_u^2}$$
(93)

where $\Delta D^* = D_{u1} - D_{u2}$ is the difference in dispersion at the IP between the two beams. This effect applies to both planes (u = x,y). In general due to the very flat beam shapes the most critical effect arises in the vertical plane.

For FCC-ee at the Z we have in vertical direction:

- Parasitic dispersion of e+ and e- beams at IP 10um the difference is $\Delta D_{\nu}^* = 14 \mu m$.
- Sigma_y is 28nm
- Sigma_E is 0.132%*45000MeV=60MeV
- Delta_ECM is therefore 1.4MeV for a 1nm offset
- Note that we cannot perform Vernier scans like at LEP, we can only displace the two beams by ~10%sigma_y
- Assume each Vernier scan is accurate to 1% sigma_y, we get a precision of 400 keV.

the process should be simulated

- we need 100 beams scans to get an E_{CM} accuracy of 40keV suggestion: vernier scan every hour or more.
- It is likely that Vernier scans will be performed regularly at least once per hour or more. (→100 per week) we end up with an uncertainty of ~10keV over the whole running period. (provided no systematic effects show up)

• The dispersion must be measured as well; this can be done by using the vernier scans with offset RF frequency

this would lead to lots of Vernier scans!

critical effect is in the vertical plane, but horizontal plane should be investigated as well

6/29/2022

beam-beam deflection scans were already used at SLC, KEK and LEP

Luminosity Optimisation Using Beam-beam Deflections at LEP

C. Bovet, M.D. Hildreth, M. Lamont, H. Schmickler, J. Wenninger, CERN, Geneva, Switzerland

CERN-SL-96-025 https://inspirehep.net/literature/420668

Uncertainty on Δy_{opt} = -5.6±0.1 µm is 1/40 of the vertical beam size 3.8±0.2 µm which was itself measured in the process

beam-beam deflection measurement at FCC-ee as if in « squished perspective » looking from behind detectors endcaps

REFERENCE

1. beams collide head on

-- or at low current

1'. pilot bunches (not colliding) all the time

1" can be calibrated with low current vernier scan

1"" or occasional vernier scan

COLLISION OFFSET

4µrad

4.2 μm

2. offset by δ_y = 0.1σ_y (=3.5nm)
→ opposite kick by 4µrad
(Shatilov) in opposite directions for e+ and e→ movement in the BPMs by ± 2 µrad x 2.1m = ±4.2 µm
(x1000 demagnification due to optics)

with a very specific pattern of movements

Vertical beam size at the IP: ~35 nm (at Z pole). Vertical offset of $0.1\sigma_{y}$ leads to additional orbit angles about $\pm 2 \mu rad$ for the nominal bunch population 2.5E+11. (*D. Shatilov, simulation*) Purely statistical and preliminary arguments (verified by J. Wenninger at last EPOL meeting)

OFFSETS:

Four measurements of 4.2 micron displacement with 1 micron precision can be made with 10⁸ bunch passages (assume 10000 bunches in each beam)

 \rightarrow every 3 seconds

CC

 \rightarrow measurement of beam beam offset with precision of 0.1 * 35nm / 4.2 / $\sqrt{4}$ = 1/80 of beam size or ~0.4nm

NB no need of a scan in principle if a good and stable reference can be demonstrated. **CAN WE USE THE PILOT BUNCHES?** LEP did not have pilot bunches, but maybe we can use them? (there is a debate on this) Pilot bunches would provide 10^8 bunch measurements in 2 minutes (only 250 bunches of each beam)

OSVD

we cannot really measure the dispersion at IP directly,

but the beams will move in opposite directions upon a change of RF frequency

 \rightarrow we measure the opposite sign vertical dispersion (OSVD) this way!

Assuming that a relative momentum change of 10-3 is feasible, this measurement corresponds to a measurement of opposite sign vertical dispersion D*y(e+)-D*y(e-) with a precision of 0.4 micrometer.

Plugging this into the equations of the earlier page this leads to a measurement of the possible shift in energy with a precision of \pm 20 keV each time the dispersion measurement is done. THIS IS VERY PROMISING because in particular it requires very little scanning across the beam.

A- Simulations of spin-tune to beam energy relationship

- -- EPFL group obtained funding from CHART for a student and a postdoc (stdies started -- Yi Wu)

Abstract

The determination of the centre-of-mass energies from the LEP1 data for 1993, 1994 and 1995 is presented. Accurate knowledge of these energies is crucial in the measurement of the Z resonance parameters. The improved understanding of the LEP energy behaviour accumulated during the 1995 energy scan is detailed, while the 1993 and 1994 measurements are revised. For 1993 these supersede the previously published values. Additional instrumentation has allowed the detection of an unexpectedly large energy rise during physics fills. This new effect is accommodated in the modelling of the beam-energy in 1995 and propagated to the 1993 and 1994 energies. New results are reported on the magnet temperature behaviour which constitutes one of the major corrections to the average LEP energy.

The 1995 energy scan took place in conditions very different from the previous years. In particular the interaction-point specific corrections to the centre-of-mass energy in 1995 are more complicated than previously: these arise from the modified radiofrequency-system configuration and from opposite-sign vertical dispersion induced by the bunch-train mode of LEP operation.

Finally an improved evaluation of the LEP centre-of-mass energy spread is presented. This significantly improves the precision on the Z width.

29/06/2

Figure 20: Polarization signal on 2 October 1991, showing the localization of the depolarizing frequency within the sweep.

Top: display of data points, with the frequency sweep indicated with vertical dashed lines. The full line represents the result of a fit with starting polarization $(-4.9\pm1.)\%$, polarization rise-time (60 ± 13) minutes, asymptotic polarization $(18.4\pm4.1)\%$.

Bottom: expanded view of the sweep period, with the individual data sets displayed (there are 10 sets per point); The frequency sweep lasted 7 data sets. The corresponding beam energy is shown in the upper box. Spin flip occurred between the two vertical dash-dotted lines.

Figure 23: Beam energy variations measured over 24 hours compared to the expectation from the tidal LEP deformation.

Many effects spoil the calibration if it is performed outside physics time

- -- tides and other ground motion
- -- RF cavity phases

Atainhistenesis effects and environmental effects (trains42etc)

Modelling of energy rise by (selected) NMR sampling of B-field is excellent !

by 1999 we had an excellent model of the energy variations... but we were not measuring the Z mass and width anymore 29/06/2022 — we were hunting for the Higgs boson!

29/06/2022

PAC 1995

- With the beam colliding at one point, a polarization level of 40 % was achieved. The polarization level was about the same for one colliding and one non colliding bunch.
- It was observed that the polarization level depends critically on the synchrotron tune : when Q_s was changed by 0.005, the polarization strongly decreased.

experiment performed at an energy of 44.71 GeV the polarization level was 40 % with a linear beam-beam tune shift of about 0.04/IP. This indicates, that the beam-beam depolarization does not scale with the linear beam-beam tune shift at one crossing point. Other parameters as spin tune and synchrotron tune are also of importance

This was only tried 3 times! Best result: P = 40%, $\xi_v^* = 0.04$, one IP

FCC-ee Assuming 2 IP and ξ^*_{γ} = 0.01 \rightarrow reduce luminosity, 10¹⁰ Z @ P~30%

Longitudinal polarization at FCC-Z?

Main interest: measure EW couplings at the Z peak most of which provide measurements of $sin^2 \theta^{lept}w = e^2/g^2 (m_z)$

(-- not to be confused with -- $sin^2\theta_W = 1 - m_w^2/m_z^2$

Useful references from the past: «polarization at LEP» CERN Yellow Report 88-02 Precision Electroweak Measurements on the Z Resonance Phys.Rept.427:257-454,2006 <u>http://arxiv.org/abs/hep-ex/0509008v3</u> GigaZ @ ILC by K. Moenig

Longitudinal polarization: reduction of polarization due to continuous injection

The colliding bunches will lose intensity continuously due to collisions. In FCC-ee with 4 IPs, L= 28 10^{34} /cm2/s beam lifetime is 213 minutes In FCC-ee with 2 IPs, L= 1.4 10^{36} /cm2/s beam life time is 55minutes

Luminosity scales inversely to beam life time. The injected e+ and e- are not polarized → asymptotic polarization is reduced. Assume here that machine has been well corrected and beams (no collisions, no injection) can be polarized to nearly maximum. (*Eliana Gianfelice in Rome talk*)

- 45 GeV
 - limit $\Delta E{=}50$ MeV (extrapolating from LEP)
 - 4 wigglers with $m{B}^+ =$ 0.7 T
 - 10% polarization in 2.9 h for energy calibration

(polarization time is 26h)

46

We have simulated the simultaneous effect of

- -- natural polarization
- -- beam consumption by e+e- interactions
- -- replenishment with unpolarized beams

assuming optimistically a maximal 90% asymptotic polarization

47

Table 4.2: The magnitude of the major common systematic errors on A_{τ} and A_{e} by category for each of the LEP experiments.

Concluding remarks

- 1. There are very strong arguments for precision energy calibration with transverse polarization at the Z peak and W threshold.
- 2. Given the likely loss in luminosity, and the intrinsic uncertainties in the extraction of the weak couplings, the case for longitudinal polarization is limited

→ We have concluded that first priority is to achieve transverse polarization in a way that allows continuous beam calibration by resonant depolarization

- this is all possible with a very high precision, both at the Z and the W. calibration at higher energies can be made from the data themselves at sufficient level.
- the question of the residual systematic error requires further studies of the relationship between beam energy and center-of-mass energy with the aim of achieving a precision of O(100 keV) on E_CM

EWRCs relations to the well measured G_F m_Z α_{QED} at first order: $\Delta \rho = \alpha / \pi (\mathbf{m}_{top} / \mathbf{m}_Z)^2$ - $\alpha / 4\pi \log (m_h / m_Z)^2$ $\varepsilon_3 = \cos^2 \theta_w \alpha / 9\pi \log (m_h/m_z)^2$ $\delta_{\rm vb} = 20/13 \, \alpha \, / \pi \, (m_{\rm top}/m_Z)^2$

complete formulae at 2d order including strong corrections are available in fitting codes

e.g. ZFITTER , GFITTER

idel

Extracting physics from $sin^2 \theta^{lept}_W$

1. Direct comparison with m_z

$$\sin^2 \Theta_w^{\text{eff}} \cos^2 \Theta_w^{\text{eff}} = \frac{\pi \alpha (M_z^2)}{\sqrt{2} G_F M_z^2} \frac{1}{1 + \Delta \rho} \frac{1}{1 - \frac{\epsilon_3}{\cos^2 \Theta_w}}$$

Uncertainties in m_{top} , $\Delta \alpha(m_z)$, m_H , etc.... $\Delta sin^2 \theta^{lept}_W \sim \Delta \alpha(m_z)/3 = 10^{-5}$ if we can reduce $\Delta \alpha(m_z)$ (see P. Janot)

2. Comparison with m_w/m_z

Compare above formula with similar one:

$$\sin^{2}\theta_{W}\cos^{2}\theta_{W} = \sqrt{2} \quad G \in \mathbb{M}_{Z}^{2} \quad \frac{1}{1 - \left(-\frac{\cos^{2}\theta_{W}}{\sin^{2}\theta_{W}}\Delta_{P} + \frac{2}{\sin^{2}\theta_{W}}\varepsilon_{3} + \frac{c^{2}-s^{2}}{s^{2}}\varepsilon_{Z}\right)}$$

Where it can be seen that $\Delta \alpha(\mathbf{m}_z)$ cancels in the relation. The limiting error is the error on \mathbf{m}_W . For $\Delta \mathbf{m}_W = 0.5$ MeV this corresponds to $\Delta \sin^2 \theta^{lept}_W = 10^{-5}$

Will consider today the contribution of the Center-of-mass energy systematic errors

Today: step I, compare ILC measurement of A_{LR} with 10⁹ Z and $P_{e_{-}}$ =80%, $P_{e_{+}}$ =30%

FCC-ee measurement of $A_{FB}^{\mu\mu}$ and $A_{FB}^{Pol}(\tau)$ with 2.10¹² Z

Comparing A_{LR} (P) and A_{FB} ($\mu\mu$)

Both measure the weak mixing angle as <u>defined</u> by the relation $A_{\ell} = \frac{(g_L^e)^2 - (g_R^e)^2}{(g_L^e)^2 + (g_R^e)^2}$

with $(g_{L}^{e}) = \frac{1}{2} - \sin^{2}\theta^{lept}_{W}$ and $(g_{R}^{e}) = -\sin^{2}\theta^{lept}_{W}$ $A_{\ell} \approx 8(1/4 - \sin^{2}\theta^{lept}_{W})$ $A_{LR} = A_{e}$ $A_{FB}^{\mu\mu} = \frac{3}{4}A_{e}A_{\mu} = \frac{3}{4}A_{\ell}^{2}$

-- A_{FB}^{μμ} is measured using muon pairs (5% of visible Z decays) and unpolarized beams
 -- A_{LR} is measured using all statistics of visible Z decays with beams of alternating longitudinal polarization both with very small experimental systematics

-- parametric sensitivity $\frac{dA_{FB}^{\mu\mu}}{d\sin^2\theta^{lept}_W} = 1.73$ vs $\frac{dA_{LR}}{d\sin^2\theta^{lept}_W} = 7.9$ -- sensitivity to center-of-mass energy (w.r.t. m_z) is larger for $A_{FB}^{\mu\mu}$ $\frac{\partial A_{FB}^{\mu\mu}}{\partial \sqrt{s}} = 0.09/\text{GeV}$ vs $\frac{\partial A_{LR}}{\partial \sqrt{s}} = 0.019/\text{GeV}$

"an 80 MeV uncertainty in Ecm corresponds to a 1% error on A_{LR} " (relative error) But of course $A_{FB}^{\mu\mu}$ benefits from much larger statistics and Ecm precision of circular collider
