# Neutrino Mass Generation: Quick Review

- Neutrino oscillation experiments provided compelling evidences for  $m_
  u 
  eq 0$
- Massive neutrinos cannot be implemented in the SM through the Yukawa int, as there are no RH neutrinos.
- However, neutrino mass can arise at higher order: (dim-5 Weinberg operator)

$$\mathcal{O}_5 = \frac{Y_{ij}^{\nu}}{\Lambda} (\bar{L}_{L_i} \tilde{H}) (\tilde{H}^T \bar{L}_{L_i}^C) + h.c. \Longrightarrow (m_{\nu})_{ij} = \frac{Y_{ij}^{\nu}}{2\Lambda} v^2$$

- Shortcoming of Weinberg operator is that it violates L by two units, hence leading to Majorana mass term, but neutrinos could also be Dirac type
- One of the most viable theoretical frameworks used to yield neutrino masses is the see-saw mechanism.

### Canonical Seesaw Mechanism

- ullet The SM Lagrangian is extended with the addition of heavy RH Majorana neutrino singlets  $N_{R_i}$
- New Yukawa interaction

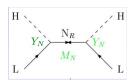

$$-\mathcal{L}_{Y} = Y_{ij}\overline{N_{R_{i}}}L_{j}H + \frac{1}{2}M_{R}\overline{N_{R_{i}}^{c}}N_{R_{j}} + \text{h.c.}$$

which gives the mass matrix in the  $(\nu_L^c, N_R)^T$  basis

$$\mathbb{M} = \begin{pmatrix} 0 & m_D \\ m_D & M_R \end{pmatrix}$$

• Upon diagonalization yields the light neutrino mass matrix as

$$m_{\nu} = Y^{T} \frac{1}{M_{P}} Y v^{2}.$$

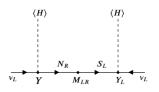

# Modified Type-I Seesaw: Linear Seesaw

- The SM is extended by three RH  $(N_{R_i})$  and three sterile  $(S_{Li})$  singlet neutrinos
- The Yukawa interaction becomes

$$-\mathcal{L}_{linear} = Y \bar{N}_R \tilde{H} L + M_{LR} \bar{N}_R S_L + Y_L \bar{L}^C \tilde{H} S_L + h.c.$$

• The mass matrix for linear seesaw in the basis  $(\nu_L, N_R, S_L^c)$ 

$$M_{linear} = \begin{pmatrix} 0 & m_D & M_{LS} \\ m_D^T & 0 & M_{LR} \\ M_{LS}^T & M_{LR}^T & 0 \end{pmatrix}$$

 The mass formula for light neutrinos evolves from the above mass matrix for M<sub>LR</sub> >> M<sub>D</sub>, M<sub>LS</sub>

$$m_{linear} = m_D M_{LR}^{-1} M_{LS}^T + \text{transpose}$$

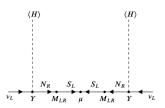

### Inverse Seesaw

- The SM is extended by three RH  $(N_{R_i})$  and three sterile  $(S_{Li})$  singlet neutrinos
- The Yukawa interaction becomes

$$-\mathcal{L}_{\textit{linear}} = Y \bar{N}_R L H + M_{LR} \bar{N}_R S_L + \mu \bar{S}^c_L S_L + h.c.$$

The mass matrix for linear seesaw is

$$M_{linear} = \begin{pmatrix} 0 & m_D & 0 \\ m_D^T & 0 & M_{LR} \\ M_{LS}^T & M_{LR}^T & \mu \end{pmatrix}$$

• The mass formula for light neutrinos for  $\mu \ll m_D \ll M_{LR}$ 

$$\emph{m}_{\emph{inv}} = \emph{m}_{\emph{D}}^{\emph{T}} (\emph{M}_{\emph{LR}}^{\emph{T}})^{-1} \emph{\mu} \emph{M}_{\emph{LR}}^{-1} \emph{m}_{\emph{D}} + \emph{h.c} \sim rac{\emph{v}^2}{\emph{M}_{\emph{LR}}^2} \emph{\mu}$$

# A<sub>4</sub> Discrete Flavor Symmetry

- Since indication of CP violation in lepton sector has been observed at T2K and NOvA, we are in the era to develop Flavor theory of leptons
- $A_4$  models are attractive, because  $A_4$  is the minimal group which has a triplet as irreducible reps: (3,1,1',1'').
- It enables us to explain the flavour symmetry:  $\mathbf{3}: (L_e, L_\mu, L_\tau), \quad \mathbf{1}: e_R, \quad \mathbf{1}': \mu_R, \quad \mathbf{1}'': \tau_R$
- ullet However, it yields a vanishing reactor mixing angle  $heta_{13}$
- Inclusion of simple perturbation by introducing the flavon fields (SM singlet scalars, but transform non-trivially under flavor group) can generate non-zero  $\theta_{13}$
- The flavons play a crucial role in determining the flavour structure due to their particular vacuum alignment.

# A<sub>4</sub> Modular Symmetry

• Modular group  $\bar{\Gamma}$  is the linear fractional transformation, acting on  $\tau$ , having the form:

$$\tau \longrightarrow \frac{a\tau + b}{c\tau + d}$$
,  $\{a, b, c, d \text{ integers}, ad - bc = 1\}$ 

• The modular group can be generated by S and T:

$$S: \quad au o -rac{1}{ au}, \quad ext{(duality)} \qquad T: \quad au o au + 1, \quad ext{(discrete shift symmetry)}$$
 which satisfy the multiplication rule  $S^2 = (ST)^3 = \mathbb{1}$ 

- The quotient group  $\Gamma_N$  is the inhomogeneous finite modular group : generators satisfy :  $S^2 = (ST)^3 = T^N = 1$
- Modular group induces  $S_3$ ,  $A_4$ ,  $S_4$  or  $A_5$  as finite quotient group; e.g.,  $\Gamma_1$  is the trivial group,  $\Gamma_2 \cong S_3$ ,  $\Gamma_3 \cong A_4$ ,  $\Gamma_4 \cong S_4$ , and  $\Gamma_5 \cong A_5$ .
- In this framework, Yukawa couplings are written in terms of modular forms, which are non-trivial representation of flavor symmetry.

### Model Framework

- ullet We consider modular  $A_4$  symmetry to study the neutrino phenomenology
- Particle spectrum enriched by six extra heavy fermion fields ( $N_{R_i}$  and  $S_{L_i}$ ) and one weighton ( $\rho$ )
- ullet The  $A_4$  and  $U(1)_X$  symmetries are considered to be broken at a scale much higher than the scale of EWSB

Fields	e <sub>R</sub> <sup>c</sup>	$\mu_R^c$	$ au_R^c$	L <sub>L</sub>	$N_R$	S <sub>L</sub>	$H_{u,d}$	ρ
SU(2) <sub>L</sub>	1	1	1	2	1	1	2	1
$U(1)_Y$	1	1	1	$-\frac{1}{2}$	0	0	$\frac{1}{2}, -\frac{1}{2}$	0
$U(1)_X$	1	1	1	-1	1	-2	0	1
$A_4$	1	1'	1"	$1,1^{\prime\prime},1^{\prime}$	3	3	1	1
k <sub>I</sub>	1	1	1	-1	-1	-1	0	0

Table: Particle content of the model and their charges under  $SU(2)_L \times U(1)_Y \times A_4$  where  $k_I$  is the modular weight.

### Model Framework

 The importance of A<sub>4</sub> modular symmetry is that less no. of flavon fields are required, as Yukawa couplings have the non-trivial group transformation

Yukawa coupling	$A_4$	kı
Υ	3	2

• The Yukawa coupling  $\mathbf{Y}=(y_1,y_2,y_3)$  with weight 2, which transforms as a triplet of  $A_4$  can be expressed in terms  $\eta(\tau)$  and its derivative

$$\begin{array}{lcl} y_{1}(\tau) & = & \frac{i}{2\pi} \left( \frac{\eta'(\tau/3)}{\eta(\tau/3)} + \frac{\eta'((\tau+1)/3)}{\eta((\tau+1)/3)} + \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} - \frac{27\eta'(3\tau)}{\eta(3\tau)} \right), \\ y_{2}(\tau) & = & \frac{-i}{\pi} \left( \frac{\eta'(\tau/3)}{\eta(\tau/3)} + \omega^{2} \frac{\eta'((\tau+1)/3)}{\eta((\tau+1)/3)} + \omega \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} \right), \\ y_{3}(\tau) & = & \frac{-i}{\pi} \left( \frac{\eta'(\tau/3)}{\eta(\tau/3)} + \omega \frac{\eta'((\tau+1)/3)}{\eta((\tau+1)/3)} + \omega^{2} \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} \right). \end{array}$$

# Masses for the Charged leptons

- The LH doublets  $(L_{e_L}, L_{\mu_L}, L_{\tau_L})$  transform as 1, 1'', 1' under  $A_4$  symmetry and are assigned  $U(1)_X$  charge of -1,  $k_I = -1$
- ullet The RH charged leptons are 1,1',1'' under  $A_4$  with  $U(1)_X$  charge +1 and  $k_I=-1$
- The relevant superpotential term for charged leptons is given by

$$\mathcal{W}_{M_\ell} = y_\ell^{ee} L_{e_L} H_d \ e_R^c + y_\ell^{\mu\mu} L_{\mu_L} H_d \ \mu_R^c + y_\ell^{\tau\tau} L_{\tau_L} H_d \ \tau_R^c \ .$$

• The charged lepton mass matrix takes the form:

$$M_{\ell} = \begin{pmatrix} y_{\ell}^{\text{ge}} v_d / \sqrt{2} & 0 & 0 \\ 0 & y_{\ell}^{\mu\mu} v_d / \sqrt{2} & 0 \\ 0 & 0 & y_{\ell}^{\tau\tau} v_d / \sqrt{2} \end{pmatrix} = \begin{pmatrix} m_e & 0 & 0 \\ 0 & m_{\mu} & 0 \\ 0 & 0 & m_{\tau} \end{pmatrix}.$$

### Dirac mass term for Neutral fermions

- The RH  $N_{R_i}$ 's transform as triplets under  $A_4$  modular group with  $U(1)_X$  charge of 1 and modular weight -1.
- The Yukawa couplings to transform as triplets under the A<sub>4</sub> with modular weight 2, so one can write invariant Dirac superpotential as

$$\mathcal{W}_D = \alpha_D L_{e_L} H_u (YN_R)_1 + \beta_D L_{\mu_L} H_u (YN_R)_{1'} + \gamma_D L_{\tau_L} H_u (YN_R)_{1''}.$$

• The resulting Dirac neutrino mass matrix is found to be

$$M_D = \frac{v_u}{\sqrt{2}} \begin{bmatrix} \alpha_D & 0 & 0 \\ 0 & \beta_D & 0 \\ 0 & 0 & \gamma_D \end{bmatrix} \begin{bmatrix} y_1 & y_3 & y_2 \\ y_2 & y_1 & y_3 \\ y_3 & y_2 & y_1 \end{bmatrix}_{IR}.$$

### Pseudo-Dirac mass term for Neutral fermions

• As we also have the extra sterile fermions  $S_{Li}$ , the pseudo-Dirac term is allowed, and the corresponding superpotential is given as

$$\mathcal{W}_{LS} = \left[\alpha_D^\prime L_{e_L} H_u \; (YS_L^c)_1 + \beta_D^\prime L_{\mu_L} H_u \; (YS_L^c)_{1^\prime} + \gamma_D^\prime L_{\tau_L} H_u \; (YS_L^c)_{1^\prime} \right] \frac{\rho^3}{\Lambda^3} \; , \label{eq:WLS}$$

 The flavor structure for the pseudo-Dirac neutrino mass matrix takes the form,

$$M_{LS} = \frac{v_u}{\sqrt{2}} \left(\frac{v_\rho}{\sqrt{2}\Lambda}\right)^3 \begin{bmatrix} \alpha_D' & 0 & 0 \\ 0 & \beta_D' & 0 \\ 0 & 0 & \gamma_D' \end{bmatrix} \begin{bmatrix} y_1 & y_3 & y_2 \\ y_2 & y_1 & y_3 \\ y_3 & y_2 & y_1 \end{bmatrix}_{IR}.$$

# Mixing between heavy Neutral fermions $N_R$ and $S_L^c$

 One can have the interactions leading to the mixing between these additional fermion field as

$$\mathcal{W}_{M_{RS}} = [\alpha_{NS} Y (S_L^c N_R)_{\text{sym}} + \beta_{NS} Y (S_L^c N_R)_{\text{Anti-sym}}] \rho$$

• Using  $\langle \rho \rangle = v_{\rho}/\sqrt{2}$ , the resulting mass matrix is

$$M_{RS} = \frac{v_{\rho}}{\sqrt{2}} \begin{pmatrix} \frac{\alpha_{NS}}{3} \begin{bmatrix} 2y_1 & -y_3 & -y_2 \\ -y_3 & 2y_2 & -y_1 \\ -y_2 & -y_1 & 2y_3 \end{bmatrix} + \beta_{NS} \begin{bmatrix} 0 & y_3 & -y_2 \\ -y_3 & 0 & y_1 \\ y_2 & -y_1 & 0 \end{bmatrix} \end{pmatrix}.$$

- $\alpha_{NS}/3 \neq \beta_{NS}$ , otherwise  $M_{RS}$  becomes singular
- The masses for the heavy fermions in the basis  $(N_R, S_L^c)^T$ , can be written as

$$M_{Hf} = \begin{pmatrix} 0 & M_{RS} \\ M_{RS}^T & 0 \end{pmatrix}.$$

• Therefore, one can have six doubly degenerate mass eigenstates for the heavy superfields upon diagonalization.

# Linear Seesaw mechanism for light neutrino Masses

• Within the present model invoked with  $A_4$  modular symmetry, the complete  $9 \times 9$  mass matrix in the flavor basis of  $(\nu_L, N_R, S_L^c)^T$  is

$$\mathbb{M} = \begin{pmatrix} & \nu_L & N_R & S_L^c \\ \hline \nu_L & 0 & M_D & M_{LS} \\ N_R & M_D^T & 0 & M_{RS} \\ S_L^c & M_{LS}^T & M_{RS}^T & 0 \end{pmatrix}.$$

• The linear seesaw mass formula for light neutrinos is given with the assumption  $M_{RS}\gg M_D, M_{LS}$  as,

$$m_{\nu} = M_D M_{RS}^{-1} M_{LS}^T + \text{transpose.}$$

• We numerically diagonalize the neutrino mass matrix through the relation  $U^{\dagger}\mathcal{M}U=\mathrm{diag}(m_1^2,m_2^2,m_3^2)$ , where  $\mathcal{M}=m_{\nu}m_{\nu}^{\dagger}$  and U is an unitary matrix

$$\sin^2 \theta_{13} = |U_{13}|^2, \quad \sin^2 \theta_{12} = \frac{|U_{12}|^2}{1 - |U_{13}|^2}, \quad \sin^2 \theta_{23} = \frac{|U_{23}|^2}{1 - |U_{13}|^2}.$$

# **Numerical Analysis**

 To fit to the current neutrino oscillation data, we chose the following ranges for the model parameters:

```
\begin{aligned} & \operatorname{Re}[\tau] \in [-0.5, 0.5], & \operatorname{Im}[\tau] \in [1, 2], & \{\alpha_D, \beta_D, \gamma_D\} \in 10^{-5} & [0.1, 1], \\ & \{\alpha_D', \beta_D', \gamma_D'\} \in 10^{-2} & [0.1, 1], & \alpha_{NS} \in [0, 0.5], & \beta_{NS} \in [0, 0.0001], \\ & \nu_\rho \in [10, 100] & \operatorname{TeV}, & \Lambda \in [100, 1000] & \operatorname{TeV}. \end{aligned}
```

- The input parameters are randomly scanned over to obtain the allowed parameter space satisfying the neutrino oscillation data and  $\sum m_i < 0.12$  eV
- The typical range of  $\tau$  is found to be:

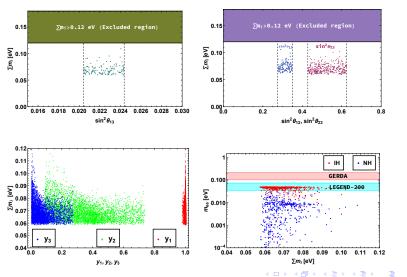

$$-0.5 \lesssim Re[\tau] \lesssim 0.5$$
 and  $1 \lesssim Im[\tau] \lesssim 2$  for NO.

• Yukawa couplings as function of  $\tau$  are found to vary in the region:

$$0.99 \lesssim y_1(\tau) \lesssim 1$$
,  $0.1 \lesssim y_2(\tau) \lesssim 0.8$  and  $0.01 \lesssim y_3(\tau) \lesssim 0.3$ .

### Some Results

# Baryon Asymmetry of the Universe

- Understanding the origin of neutrino mass and BAU are two major challenges in Particle Physics
- Leptogenesis plays a vital role in relating these two issues
- The BAU is parametrized in terms of the following quantity:

$$\eta \equiv \frac{n_B - n_{\bar{B}}}{n_{\gamma}} = (6.12 \pm 0.04) \times 10^{-10}$$

 An alternative way to express matter-antimatter asymmetry is to use the ratio

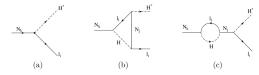

$$Y_B = \frac{n_B - n_{\bar{B}}}{s}$$

• The two formulations in terms of  $Y_B$  and  $\eta$ , at the present time, are easily related:

$$Y_B = \frac{n_\gamma^0}{s^0} \eta = 0.142 \eta = (8.77 \pm 0.24) \times 10^{-11}.$$

# Resonant Leptogenesis

• For quasi-degenerate heavy Majorana neutrinos, i.e.,  $M_{N_i} - M_{N_j} \ll M_{N_i}$ , the self energy  $(\varepsilon)$  contribution to the CP asymmetry becomes dominant

- Resonant leptogenesis occurs when  $M_{N_i} M_{N_j} \sim \Gamma_{N_i}$ , in this case CP asymmetry can become very large (even order 1)
- The  $\varepsilon$ -type CP asymmetry,

$$\varepsilon_{N_{i}} = \frac{\mathrm{Im}(h^{\nu\dagger}h^{\nu})_{ij}^{2}}{(h^{\nu\dagger}h^{\nu})_{ii}(h^{\nu\dagger}h^{\nu})_{jj}} \frac{(m_{N_{i}}^{2} - m_{N_{j}}^{2})m_{N_{i}}\Gamma_{N_{j}}^{(0)}}{(m_{N_{i}}^{2} - m_{N_{i}}^{2})^{2} + m_{N_{i}}^{2}\Gamma_{N_{i}}^{(0)}}^{2}$$

 $\circ$   $\mathcal{O}(1)$  CP asymmetries are possible when,

$$m_{N_2} - m_{N_1} \sim \frac{1}{2} \Gamma^{(0)}_{N_{1,2}}, \qquad \frac{\operatorname{Im}(h^{\nu\dagger}h^{\nu})_{ij}^2}{(h^{\nu\dagger}h^{\nu})_{ii}(h^{\nu\dagger}h^{\nu})_{jj}} \sim 1$$

# Resonant Leptogenesis in the present framework

 Six heavy states with doubly degenerate masses for each pair, obtained by diagonalization of the heavy fermion mass matrix

$$M_{Hf} = \begin{pmatrix} 0 & M_{RS} \\ M_{RS}^T & 0 \end{pmatrix}$$

 But one can introduce a higher dimensional mass term for the heavy RH neutrinos (N<sub>R</sub>) as

$$L_M = -\alpha_R Y N_R^c N_R^c \frac{\rho^2}{\Lambda}$$

• Thus, one can construct the right-handed Majorana mass matrix as

$$M_R = rac{lpha_R v_{
ho}^2}{6\Lambda} egin{pmatrix} 2y_1 & -y_3 & -y_2 \\ -y_3 & 2y_2 & -y_1 \\ -y_2 & -y_1 & 2y_3 \end{pmatrix}.$$

•  $\alpha_R$  is extremely small to retain the linear seesaw structure of the mass matrix i.e.,  $M_D, M_{LS} \gg M_R$ 

### Leptogenesis cont.

Block diagonalization of the mass matrix yields:

$$M' = \begin{pmatrix} M_{RS} + \frac{M_R}{2} & -\frac{M_R}{2} \\ -\frac{M_R}{2} & -M_{RS} + \frac{M_R}{2} \end{pmatrix} \approx \begin{pmatrix} M_{RS} + \frac{M_R}{2} & 0 \\ 0 & -M_{RS} + \frac{M_R}{2} \end{pmatrix}.$$

ullet And the mass eigenstates  $(N^\pm)$  are related to  $N_R$  and  $S_L^c$  through

$$\begin{pmatrix} S_{Li}^c \\ N_{Ri} \end{pmatrix} = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} N_i^+ \\ N_i^- \end{pmatrix}.$$

ullet The mass eigenvalues for the new states  $N^+$  and  $N^-$  can be expressed as

$$M_{RS} \pm \frac{M_R}{2} = \left(\frac{\alpha_{NS} v_{\rho}}{\sqrt{2}} \pm \frac{\alpha_R v_{\rho}^2}{4\Lambda}\right) \begin{pmatrix} 2y_1 & -y_3 & -y_2 \\ -y_3 & 2y_2 & -y_1 \\ -y_2 & -y_1 & 2y_3 \end{pmatrix}.$$

 The lightest pair, assumed to be in the TeV scale, dominantly contribute to the CP asymmetry, i.e., the contribution from one loop self energy dominates over the vertex diagram.

# One Flavor Approximation

- The evolution of lepton asymmetry can be deduced from the Boltzmann equations.
- Sakharov criteria demand the decay of parent fermion to be out of equilibrium to generate the lepton asymmetry.
- To impose this condition, one has to compare the Hubble rate with the decay rate

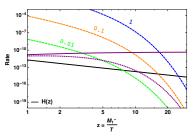

$$K = \frac{\Gamma_{N_1^-}}{H(T = M_1^-)} \ .$$

 The Boltzmann equations for the evolution of the number densities of RH fermions, in terms of yield parameter

$$\begin{split} \frac{dY_{N^-}}{dz} &= -\frac{z}{sH(M_1^-)} \left[ \left( \frac{Y_{N^-}}{Y_{N^-}^{\text{eq}}} - 1 \right) \gamma_D + \left( \left( \frac{Y_{N^-}}{Y_{N^-}^{\text{eq}}} \right)^2 - 1 \right) \gamma_S \right], \\ \frac{dY_{B-L}}{dz} &= -\frac{z}{sH(M_1^-)} \left[ \epsilon_{N^-} \left( \frac{Y_{N^-}}{Y_{N^-}^{\text{eq}}} - 1 \right) \gamma_D - \frac{Y_{B-L}}{Y_{\ell}^{\text{eq}}} \frac{\gamma_D}{2} \right] \end{split}$$

# One Flavor Approximation

- Decay  $(\Gamma_D)$  in Purple solid line and inverse decay  $\left(\Gamma_D \frac{\gamma_{N-}^{\rm eq}}{\gamma_{\ell}^{\rm eq}}\right)$  dotted purple line with the coupling strength  $\sim 10^{-6}$ .
- The scattering rate  $\left(\frac{\gamma_S}{sY_{N^-}^{\rm eq}}\right)$  for  $N_1^-N_1^- \to \rho\rho$  is projected for various set of values for coupling, consistent with neutrino oscillation study.

# One Flavor Approximation

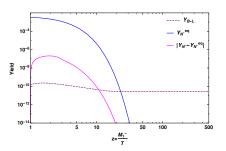

Figure: Evolution of  $Y_{B-L}$  (dashed) as a function of  $z = M_1^-/T$ .

 The obtained lepton asymmetry gets converted to the observed baryon asymmetry through sphaleron transition

$$Y_B = \left(\frac{8N_f + 4N_H}{22N_f + 13N_H}\right)Y_{B-L} \sim \mathcal{O}(10^{-10}).$$

### Conclusion

- The modular A<sub>4</sub> flavor symmetry is quite successful in accommodating the observed neutrino oscillation data.
- The important aspect of modular symmetry is that the Yukawa couplings to transform non-trivially under modular A<sub>4</sub> group, which replaces the role of conventional flavon fields.
- Leptogenesis can be explained through the decay of lightest heavy fermion eigenstate
- It is found that the evolution of lepton asymmetry at TeV scale comes out to be of the order  $\approx 10^{-10}$ , which is sufficient to explain the present baryon asymmetry of the Universe.

Thank you for your attention!
