Cosmic Strings

Introduction

Cosmic strings are linear topological defects in a quantum field theory. They are analogous to line defects in a crystal and vortex lines in superfluids or superconductors.

- 1st analog: line defect in a crystal
- 2nd analog: vortex line in superfluid or superconductor

Cosmic strings are lines of trapped energy density in a quantum field theory, which can give rise to gravitational effects on space-time and are important in cosmology.

Trapped energy density → gravitational effects on space-time → important in cosmology.

Cosmic strings are predicted in many particle physics models beyond the “Standard Model”.

Cosmic strings are predicted to form at the end of inflation in many inflationary models.

Cosmic strings may survive as cosmic superstrings in alternatives to inflation such as string gas cosmology.

In models which admit cosmic strings, cosmic strings inevitably form in the early universe and persist to the present time.

Cosmic strings are characterized by their tension $\mu$ which is associated with the energy scale $\eta$ at which the strings form ($\mu \sim \eta^2$).

Searching for the signatures of cosmic strings is a tool to probe physics beyond the Standard Model at energy ranges complementary to those probed by the LHC.

Cosmic strings are constrained from cosmology: strings with a tension which exceed the value $G\mu \sim 3 \times 10^{-7}$ are in conflict with the observed acoustic oscillations in the CMB angular power spectrum.

Existing upper bound on the string tension rules out large classes of particle physics models.

It is interesting to find ways to possibly lower the bounds on the string tension.

Cosmic strings can produce many good things for cosmology:

- Explanation for the origin of primordial magnetic fields which are coherent on galactic scales (X. Zhang and R.B. (1999).

It is interesting to find evidence for the possible existence of cosmic strings.
Cosmic strings can produce many good things for cosmology:

Important lessons from this talk:

- Cosmic strings → nonlinearities already at high redshifts.
- Signatures of cosmic strings more pronounced at high redshifts.
- Cosmic strings lead to perturbations which are non-Gaussian.
- Cosmic strings predict specific geometrical patterns in position space.
- 21 cm surveys provide an ideal arena to look for cosmic strings (R.B., R. Danos, O. Hernandez and G. Holder, 2010).
Cosmic strings form after symmetry breaking phase transitions.

Prototypical example: Complex scalar field $\phi$ with “Mexican hat" potential:

$$V(\phi) = \frac{\lambda}{4} \left( |\phi|^2 - \eta^2 \right)^2$$

Vacuum manifold $\mathcal{M}$: set up field values which minimize $V$. 
Cosmic strings form after symmetry breaking phase transitions.

Prototypical example: Complex scalar field $\phi$ with “Mexican hat" potential:

$$V(\phi) = \frac{\lambda}{4} (|\phi|^2 - \eta^2)^2$$

Vacuum manifold $M$: set up field values which minimize $V$. 
Cosmic strings form after symmetry breaking phase transitions.

Prototypical example: Complex scalar field $\phi$ with “Mexican hat” potential:

$$V(\phi) = \frac{\lambda}{4} (|\phi|^2 - \eta^2)^2$$

Vacuum manifold $\mathcal{M}$: set up field values which minimize $V$.

At high temperature: $\phi = 0$.

At low temperature: $|\phi| = \eta$ - but not at all $x$.

Cosmic string core: points with $|\phi| \ll \eta$.

Criterium for the existence of cosmic strings: $\Pi_1(\mathcal{M}) \neq \infty$.

Cosmic String I
Cosmic strings form after symmetry breaking phase transitions.

Prototypical example: Complex scalar field $\phi$ with "Mexican hat" potential:

$$V(\phi) = \frac{\lambda}{4} (|\phi|^2 - \eta^2)^2$$

Vacuum manifold $\mathcal{M}$: set up field values which minimize $V$.

At high temperature: $\phi = 0$.

At low temperature: $|\phi| = \eta$ - but not at all $x$.

Cosmic string core: points with $|\phi| \ll \eta$.

Criterium for the existence of cosmic strings: $\Pi_1(\mathcal{M}) \neq \infty$. 

Symmetric cosmic string configuration (uniform along z axis, with core at $\rho = 0$):

$$\phi(\rho, \theta) = f(\rho) \eta e^{i\theta}$$

- $f(\rho) \rightarrow 1$ for $\rho > w$
- $f(\rho) \rightarrow 0$ for $\rho < w$

Important features:

- **Width** $w \sim \lambda^{-1/2} \eta^{-1}$
- **Mass per unit length** $\mu \sim \eta^2$ (independent of $\lambda$).
By causality, the values of $\phi$ in $\mathcal{M}$ cannot be correlated on scales larger than $t$.

Hence, there is a probability $O(1)$ that there is a string passing through a surface of side length $t$.

If the field $\phi$ is in thermal equilibrium above the phase transition temperature, then the actual correlation length of the string network (mean separation and curvature radius of the network of infinite strings) is microscopic, given by the “Ginsburg length" $\lambda^{-1} \eta^{-1}$. 
By causality, the values of $\phi$ in $\mathcal{M}$ cannot be correlated on scales larger than $t$.

Conclusions

Scaling Solution I

Causality $\rightarrow$ network of cosmic strings persists at all times.

Correlation length $\xi(t) < t$ for all times $t > t_c$.

Dynamics of $\xi(t)$ is governed by a Boltzmann equation which describes the transfer of energy from long strings to string loops.
Analysis of the Boltzmann equation shows that $\xi(t) \sim t$ for all $t > t_c$:

- If $\xi(t) \ll t$ then rapid loop production and $\xi(t)/t$ increases.
- If $\xi(t) \gg t$ then no loop production and $\xi(t)/t$ decreases.

Sketch of the scaling solution:
Cosmic strings were popular in the 1980’s as an alternative to inflation for producing a scale-invariant spectrum of cosmological perturbations.

Cosmic strings lead to incoherent and active fluctuations (rather than coherent and passive like in inflation).

Reason: strings on super-Hubble scales are entropy fluctuations which seed an adiabatic mode which is growing until Hubble radius crossing.

Boomerang CMB data (1999) on the acoustic oscillations in the CMB angular power spectrum rules out cosmic strings as the main source of fluctuations.

Interest in cosmic strings collapses.
Supergravity models of inflation typically yield cosmic strings after reheating (R. Jeannerot et al., 2003).

Brane inflation models typically yield cosmic strings in the form of cosmic superstrings (Sarangi and Tye, 2002).

→ renewed interest in cosmic strings as supplementary source of fluctuations.

Best current limit from angular spectrum of CMB anisotropies: $\sim 10\%$ of the total power can come from strings (see e.g. Wyman, Pogosian and Wasserman, 2005).

Leads to limit $G_\mu < 3 \times 10^{-7}$.

Geometry of a Straight String

Space away from the string is **locally flat** (cosmic string exerts no gravitational pull).

Space perpendicular to a string is **conical with deficit angle**

\[ \alpha = 8\pi G\mu, \]
Photons passing by the string undergo a relative Doppler shift

$$\frac{\delta T}{T} = 8\pi \gamma(v) v G \mu,$$
→ network of line discontinuities in CMB anisotropy maps.

*N.B. characteristic scale: comoving Hubble radius at the time of recombination* → *need good angular resolution to detect these edges.*

Need to analyze position space maps.
Signature in CMB temperature anisotropy maps

$10^0 \times 10^0$ map of the sky at 1.5’ resolution
→ network of line discontinuities in CMB anisotropy maps.

Characteristic scale: comoving Hubble radius at the time of recombination → need good angular resolution to detect these edges.

Need to analyze position space maps.

Edges produced by cosmic strings are masked by the "background" noise.
Temperature map Gaussian + strings
→ network of line discontinuities in CMB anisotropy maps.

Characteristic scale: comoving Hubble radius at the time of recombination → need good angular resolution to detect these edges.

Need to analyze position space maps.

Edges produced by cosmic strings are masked by the "background" noise.

Edge detection algorithms: a promising way to search for strings

Consider a cosmic string moving through the primordial gas:

Wedge-shaped region of overdensity 2 builds up behind the moving string: wake.

\[ \delta v = 4\pi G \mu V \gamma(V) \]
Consider a string at time $t_i [t_{rec} < t_i < t_0]$ moving with velocity $v_s$ with typical curvature radius $c_1 t_i$. 

Closer look at the wedge:

- $4\pi G \mu t_i v_s \gamma_S$
- $t_i v_s \gamma_S$
Gravitational accretion onto a wake

- **Initial overdensity** → **gravitational accretion onto the wake**.
- Accretion computed using the Zeldovich approximation.
- Focus on a mass shell a physical distance $w(q, t)$ above the wake:
  \[
  w(q, t) = a(t)(q - \psi),
  \]
- Gravitational accretion → $\psi$ grows.
- **Turnaround**: $\dot{w}(q, t) = 0$ determines $q_{nl}(t)$ and thus the thickness of the gravitationally bound region.
Gravitational accretion onto a wake

- Initial overdensity $\rightarrow$ gravitational accretion onto the wake.
- Accretion computed using the Zeldovich approximation.
- Focus on a mass shell a physical distance $w(q, t)$ above the wake:

\[
    w(q, t) = a(t)(q - \psi),
\]

- Gravitational accretion $\rightarrow$ $\psi$ grows.
- Turnaround: $\dot{w}(q, t) = 0$ determines $q_{nl}(t)$ and thus the thickness of the gravitationally bound region.
Gravitational accretion onto a wake

- Initial overdensity $\rightarrow$ gravitational accretion onto the wake.
- Accretion computed using the Zeldovich approximation.
- Focus on a mass shell a physical distance $w(q, t)$ above the wake:

$$w(q, t) = a(t)(q - \psi) ,$$

- Gravitational accretion $\rightarrow$ $\psi$ grows.
- Turnaround: $\dot{w}(q, t) = 0$ determines $q_{nl}(t)$ and thus the thickness of the gravitationally bound region.
Wake is a region of enhanced free electrons.

CMB photons emitted at the time of recombination acquire extra polarization when they pass through a wake.

Statistically an equal strength of E-mode and B-mode polarization is generated.

Consider photons which at time \( t \) pass through a string segment laid down at time \( t_i < t \).

\[
\frac{P}{Q} \simeq \frac{24\pi}{25} \left( \frac{3}{4\pi} \right)^{1/2} \sigma_T fG\mu v\gamma_s \\
\times \Omega_B \rho_c(t_0) m_p^{-1} t_0(z(t) + 1)^2 (z(t_i) + 1)^{1/2}.
\]
Inserting numbers yields the result:

\[
\frac{P}{Q} \sim fG\mu v_s \gamma_s \Omega_B \left( \frac{z(t) + 1}{10^3} \right)^2 \left( \frac{z(t_i) + 1}{10^3} \right)^3 \times 10^7 .
\]

Characteristic pattern in position space:
Cosmic strings produce direct B-mode polarization.

- gravitational waves not the only source of primordial B-mode polarization.
- Cosmic string loop oscillations produce a scale-invariant spectrum of primordial gravitational waves with a contribution to $\delta T/T$ which is comparable to that induced by scalar fluctuations (see e.g. A. Albrecht, R.B. and N. Turok, 1986).
- a detection of gravitational waves through B-mode polarization is more likely to be a sign of something different than inflation.
**Cosmic strings produce direct B-mode polarization.**

→ **gravitational waves not the only source of primordial B-mode polarization.**

**Cosmic string loop oscillations produce a scale-invariant spectrum of primordial gravitational waves with a contribution to $\delta T / T$ which is comparable to that induced by scalar fluctuations (see e.g. A. Albrecht, R.B. and N. Turok, 1986).**

→ **a detection of gravitational waves through B-mode polarization is more likely to be a sign of something different than inflation.**

→ a detection of gravitational waves through B-mode polarization is more likely to be a sign of something different than inflation.
N.B. **String Gas Cosmology** produces a spectrum of gravitational waves with an amplitude larger than in many single field inflation models and with a small **blue tilt**.

- Inflationary cosmology must produce a red tilt.
- Observing a blue tilt of the gravitational wave spectrum would falsify inflationary cosmology.
- B-mode polarization may be the holy grail of early universe cosmology, but not of inflation.

The Effect

- $10^3 > z > 10$: baryonic matter dominated by neutral H.
- Neutral H has hydrogen hyperfine absorption/emission line.
- String wake is a gas cloud with special geometry which emits/absorbs 21cm radiation.
- Whether signal is emission/absorption depends on the temperature of the gas cloud.
The Effect

- $10^3 > z > 10$: baryonic matter dominated by neutral H.
- Neutral H has hydrogen hyperfine absorption/emission line.

Signatures of Cosmic Strings in 21cm Maps

Conclusions
Key general formulas

Brightness temperature:

\[ T_b(\nu) = T_S(1 - e^{-\tau_\nu}) + T_\gamma(\nu)e^{-\tau_\nu}, \]

Spin temperature:

\[ T_S = \frac{1 + x_c}{1 + x_c T_\gamma/T_K} T_\gamma. \]

\( T_K \): gas temperature in the wake, \( x_c \) collision coefficient

Relative brightness temperature:

\[ \delta T_b(\nu) = \frac{T_b(\nu) - T_\gamma(\nu)}{1 + z} \]
Optical depth:

\[ \tau_\nu = \frac{3c^2 A_{10}}{4\nu^2} \left( \frac{\hbar \nu}{k_B T_S} \right) \frac{N_{HI}}{4} \phi(\nu), \]

Frequency dispersion

\[ \frac{\delta \nu}{\nu} = 2\sin(\theta) \tan \theta \frac{H_w}{c}, \]

Line profile:

\[ \phi(\nu) = \frac{1}{\delta \nu} \text{ for } \nu \in \left[ \nu_{10} - \frac{\delta \nu}{2}, \nu_{10} + \frac{\delta \nu}{2} \right], \]
Application to Cosmic String Wakes

Wake temperature $T_K$:

$$T_K \simeq [20 \text{ K}] (G\mu)^2 (v_s\gamma_s)^2 \frac{Z_i + 1}{Z + 1},$$

determined by considering thermalization at the shock which occurs after turnaround when $w = 1/2w_{max}$ (see Eulerian hydro simulations by A. Sornborger et al, 1997).

Thickness in redshift space:

$$\frac{\delta \nu}{\nu} = \frac{24\pi}{15} G\mu v_s\gamma_s (Z_i + 1)^{1/2} (Z(t) + 1)^{-1/2}$$

$$\simeq 3 \times 10^{-5} (G\mu)_6 (v_s\gamma_s),$$

using $z_i + 1 = 10^3$ and $z + 1 = 30$ in the second line.
Application to Cosmic String Wakes

Wake temperature $T_K$:

$$T_K \simeq [20 \text{ K}](G\mu)^2(v_s\gamma_s)^2\frac{Z_i + 1}{z + 1},$$

determined by considering thermalization at the shock which occurs after turnaround when $w = \frac{1}{2}w_{max}$ (see Eulerian hydro simulations by A. Sornborger et al, 1997).

Thickness in redshift space:

$$\frac{\delta \nu}{\nu} = \frac{24\pi}{15} G\mu v_s\gamma_s(Z_i + 1)^{1/2}(Z(t) + 1)^{-1/2}$$

$$\simeq 3 \times 10^{-5} (G\mu)_6(v_s\gamma_s),$$

using $Z_i + 1 = 10^3$ and $z + 1 = 30$ in the second line.
Relative brightness temperature:

\[ \delta T_b(\nu) = [0.07 \, \text{K}] \frac{x_c}{1 + x_c} \left(1 - \frac{T_\gamma}{T_K}\right)(1 + z)^{1/2} \]
\[ \sim 200 \, \text{mK} \quad \text{for} \quad z + 1 = 30. \]

Signal is emission if \( T_K > T_\gamma \) and absorption otherwise.

Critical curve (transition from emission to absorption):

\[ (G\mu)_6^2 \sim 0.1 (v_s\gamma_s)^{-2} \frac{(z + 1)^2}{Z_i + 1} \]
Relative brightness temperature:

\[ \delta T_b(\nu) = [0.07 \, \text{K}] \frac{x_c}{1 + x_c} \left(1 - \frac{T_\gamma}{T_K}\right)(1 + z)^{1/2} \]
\[ \sim 200 \, \text{mK} \quad \text{for} \quad z + 1 = 30. \]

Signal is emission if \( T_K > T_\gamma \) and absorption otherwise.

Critical curve (transition from emission to absorption):

\[ (G_\mu)_6 \simeq 0.1 (v_s \gamma_s)^{-2} \frac{(z + 1)^2}{Z_i + 1} \]
Scalings of various temperatures

Top curve: \((G_\mu)_6 = 1\), bottom curve: \((G_\mu)_6 = 0.3\)
