ICMC 2023

July 10, 2023

# Summary

- AlBeMet AM162H
- Mass specific resistivity comparison and resistivity of AlBeMet AM162H versus state-of-the-art cryoresistive materials
- Magnetoresistance of AlBeMet AM162H
- DC current carrying capacity of AlBeMet AM162H versus state-of-the-art cryoresistive materials and REBCO coated conductor
- AlBeMet AM162H current leads
- AlBeMet AM162H for low AC loss conductors
- Future Work

# AlBeMet AM162H, an Al-Be Nanocomposite

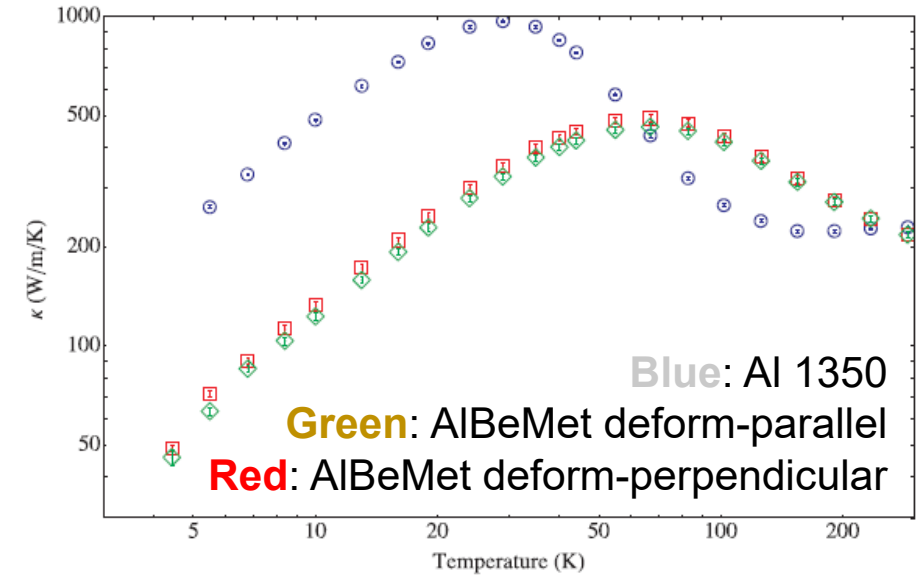

- Beryllium is an amazing material, but hard to process (machining, bonding, etc.)
- AlBeMet AM162H 38%wt Al matrix, 62%wt Be reinforced composite (not an alloy, nanocomposite)
- AlBeMet AM162H is machinable, bondable, and processable as other Al aerospace grade alloys

- AlBeMet AM162H:
  - High  $\kappa$  (RT=250 W/mK)
  - High E (RT=200 GPa)
  - Low  $\rho$  (2.1 g/cm<sup>3</sup>)
  - High  $\sigma_y$  (RT>300 MPa)

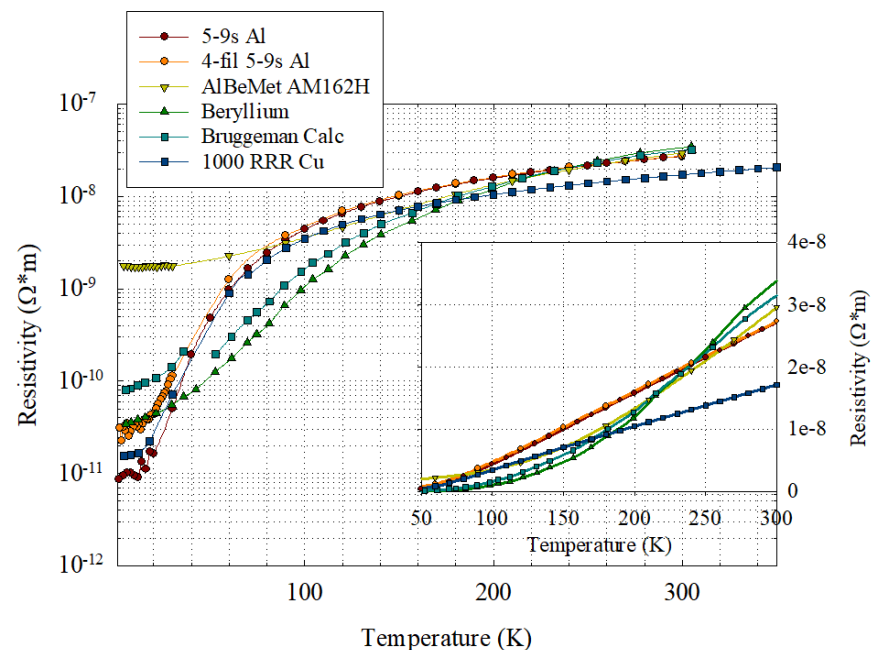

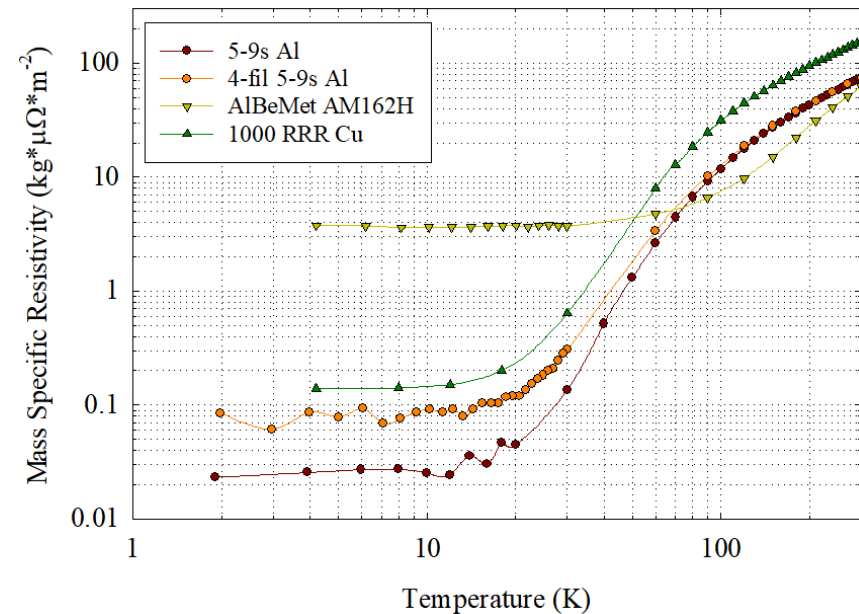

- What about cryogenic electrical resistivity and magnetoresistance?

# Mass Specific Resistivity

- Mass specific electrical resistivity (MSR) is an important material metric for aerospace
- Density multiplied by resistivity (small is good)
- Be has the lowest mass specific resistivity of any structural rated and chemically stable metal, next up is Al
- Be hard to shape and bond, AlBeMet AM162H is not
- Be  $\rho_{elec} < Cu$  starting from 180K
- AlBeMet AM162 (RRR=17)  $\rho_{elec} < Cu$  105K to 150K
- AlBeMet AM162 (RRR=17)  $\rho_{elec} < Cu$  105K to 150K
- AlBeMet AM162 MSR < Al greater than RT to 75 K

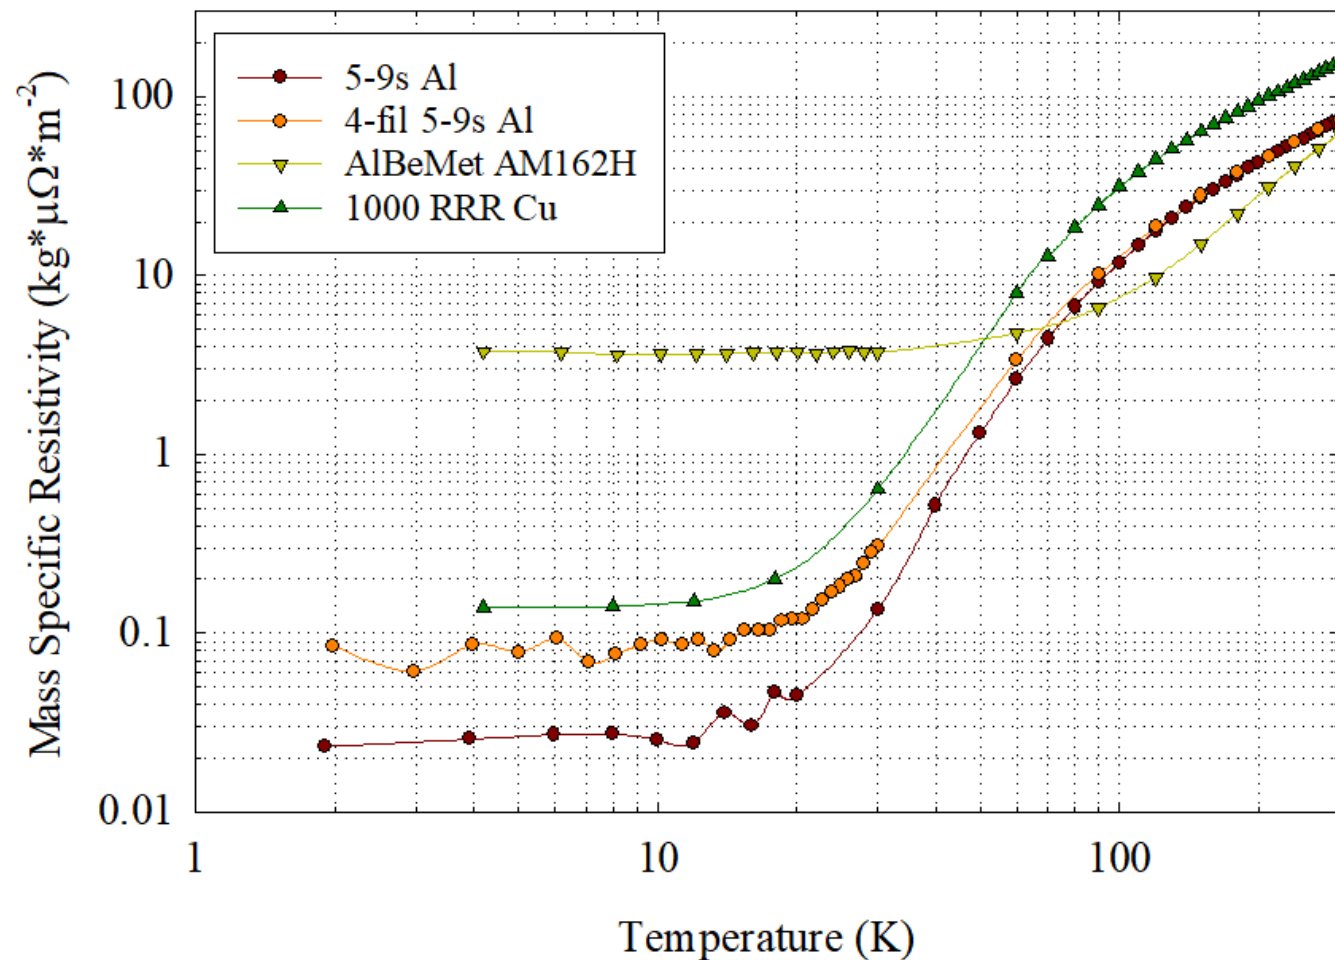

$$\rho_{eff} = \rho_m \times \frac{2\theta_i(\rho_i - \rho_m) + \rho_i + 2\rho_m}{2\rho_m + \rho_i - \theta_i(\rho_i - \rho_m)}$$

Bruggeman effective medium approximation  
Composite resistivity "rule-of-mixtures"

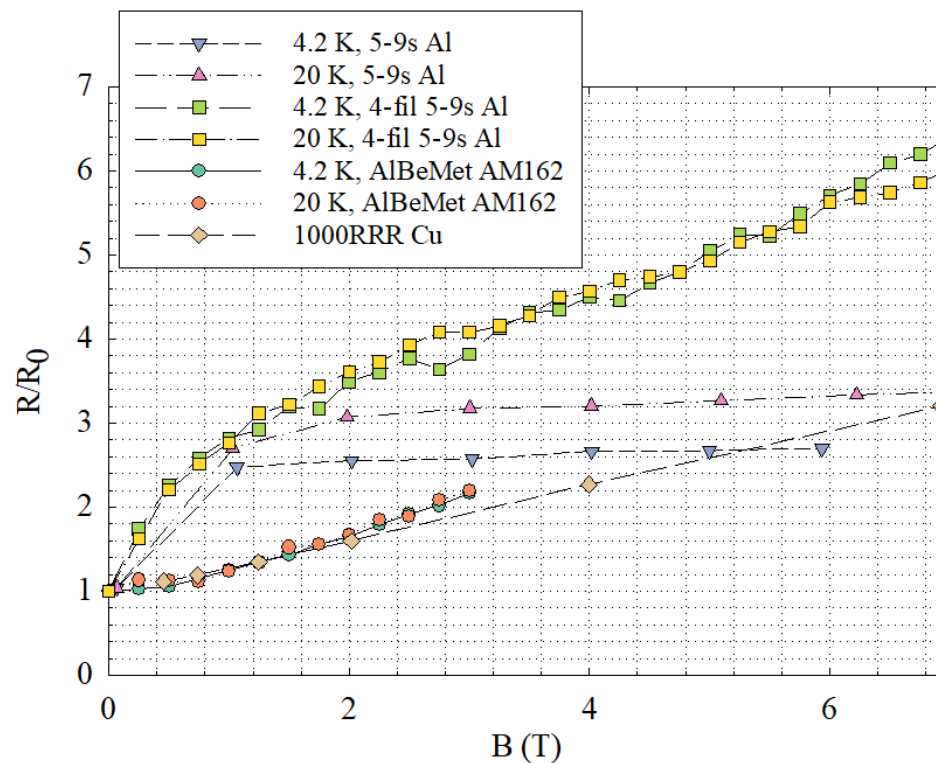

# Note on AlBeMet Cryogenic MSR

- AlBeMet AM162H metal powders are high purity Al 1100 and Be (grade B-26-D)
- Annealed (593C x 24hr) AlBeMet AM162H is RRR = 17 even though predicted much lower from Bloch-Gruneisen resistivity + Bruggeman effective medium approximation for composites.
- High electron scattering at composite interfaces, which becomes more relevant with increases of mean free path at cryogenic temperatures ( $l_{MFP}$  is proportional to  $1/\rho_{elec}$ )
- Tough to avoid oxygen contamination from high surface area metal powders

# Magneto-resistance of AlBeMet vs. Other Cryoresistive Options

- Cu follows Kohler plot well, 5-9s Al not so well, [Fickett (1971)]
- “Anomalous magneto-resistance” in 5-9s multifilamentary wire is large
  - New composites reduce this (see OSU/HTR research M3Or4M-03)
- AlBeMet AM162H magneto-resistance is similar to Cu, and smaller than 5-9s Al up to 3 T.
- At 4.2 K and 20K AlBeMet AM162H is much higher resistivity than other state-of-the-art cryoconductors

Fickett “Aluminum 1. A Review of Resistive Mechanisms in Aluminum” (1971)  
 Eckels “Magneto-resistance in Composite Conductors” (1990)

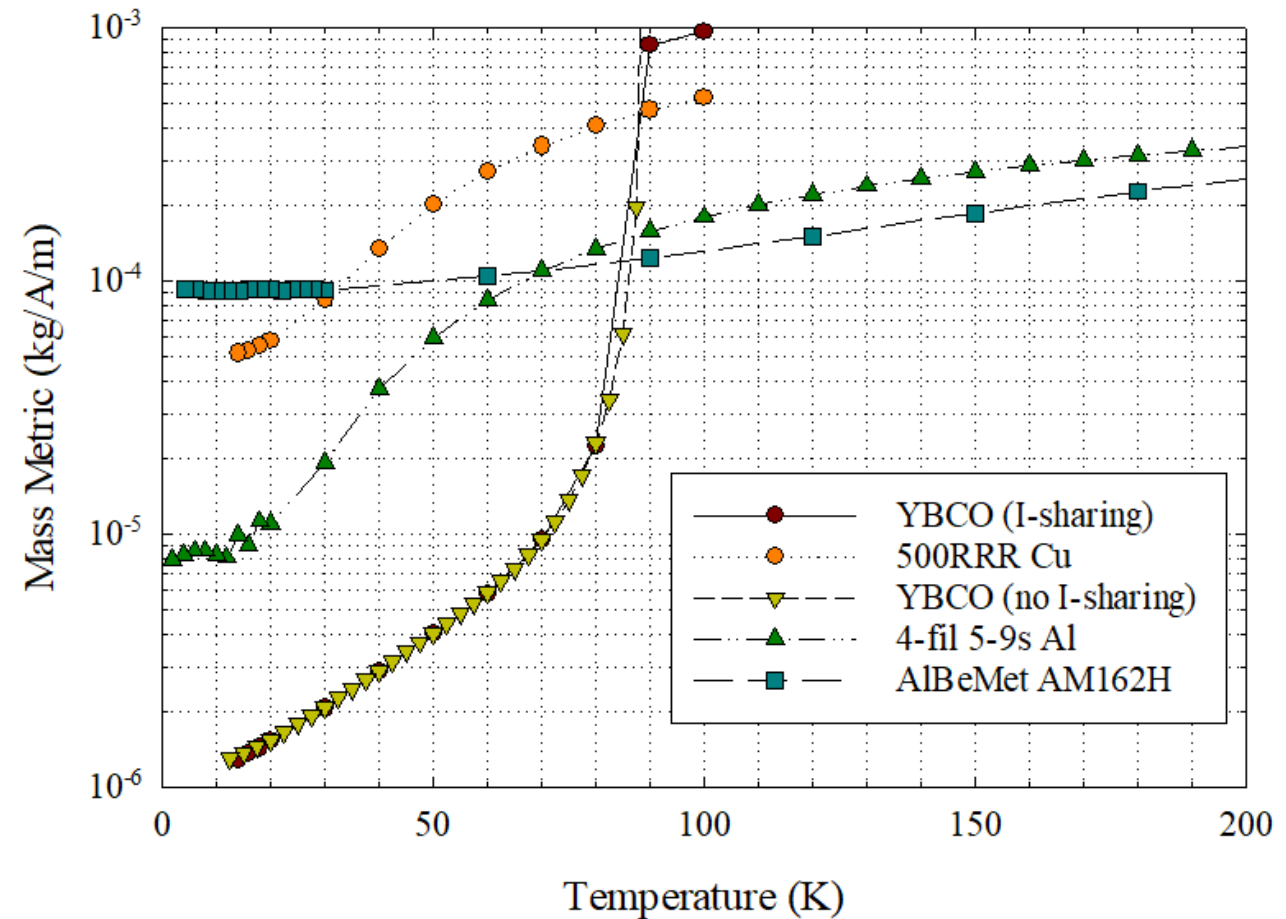

# DC “Ampacity” of Cryoresistive and Superconducting Options

- “Current carrying capacity”, known as Ampacity, is a function of effective cooling rate and resistivity of the ohmic material
  - For unit cross section and unit length:
  - $J_{e-ampacity} [A/m^2] = \frac{Q [\frac{W}{m}]}{\rho_{elec} \times l}$  and
  - $J_{e-ampacity} [A/m^2] = \sqrt{\frac{Q [\frac{W}{m^3}]}{\rho_{elec}}}$
  - Where “Q” is a known cooling-rate and “l” is current
  - Knowing current, it is then possible to calculate the safe cross-sectional area of a wire/cable.
  - Can also calculate an important performance metric which is mass density divided by ampacity [kg/(A\*m)] (smaller is better)
- Ampacity also exists in superconducting composites. Incorporating current sharing with the stabilizer increases ampacity to greater than  $J_c$ .
  - $J_{e-ampacity(SC\ composite)} [A/m^2] = \frac{J_{c-eng} \times A_{tot} + J_{e-ampacity(stabilizer)} \times A_{stabilizer}}{A_{tot}}$
  - Where “ $A_{tot}$  and  $A_{stabilizer}$ ” is total cross-sectional area of the superconducting composite and stabilizer respectively and “ $J_{c-eng}$ ” is the critical current density of the superconducting composite.

# DC “Ampacity” of Cryoresistive and Superconducting Options

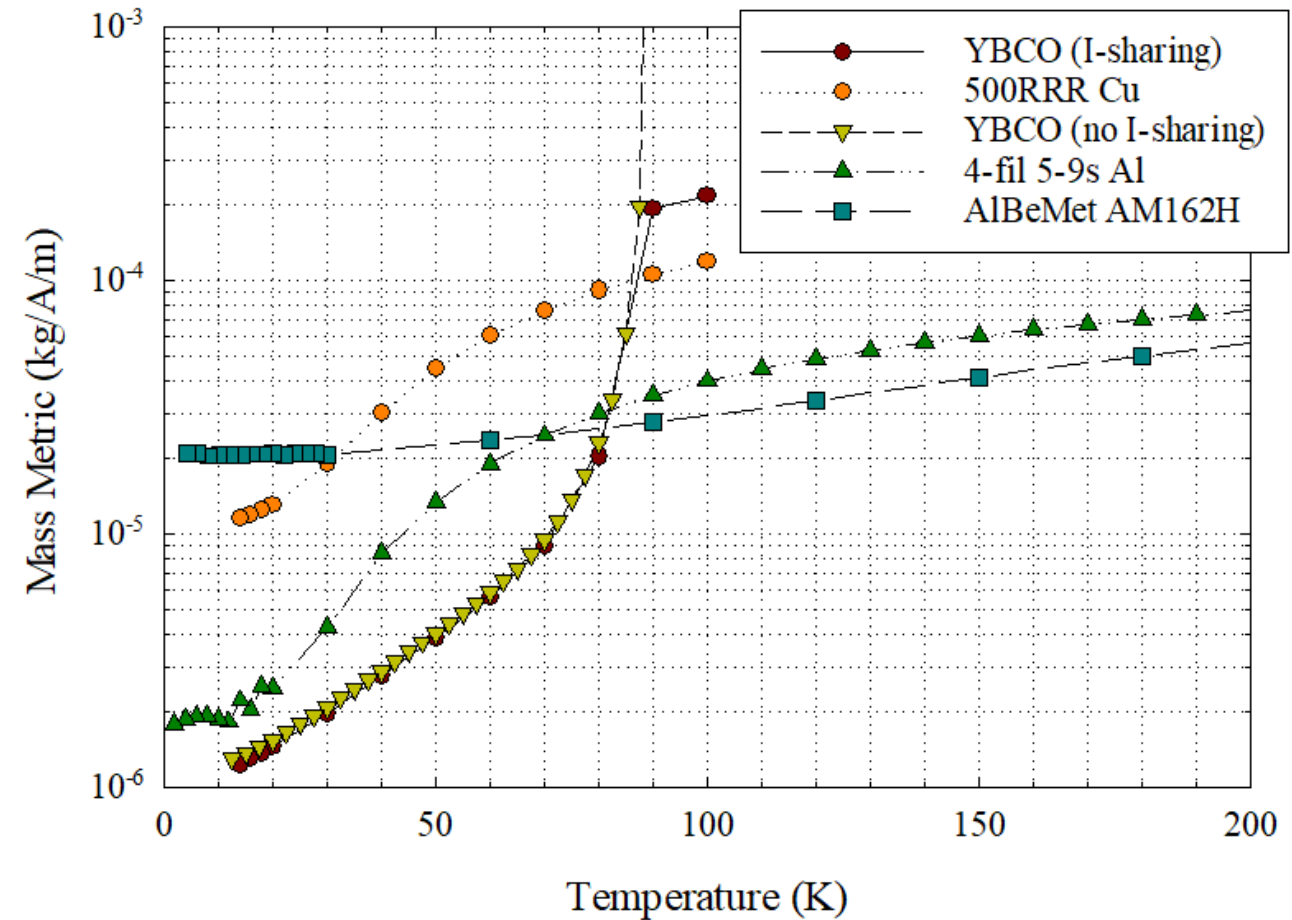

- Ampacity is a strong function of available cooling
- This comparison is for:
  - High performance YBCO ( $I_c$  data for AP Superpower tape [<https://htsdb.wimbush.eu/>]) customized with a 20  $\mu\text{m}$  thick 500RRR Cu stabilizer and 30  $\mu\text{m}$  substrate.
  - $Q = 1 \text{ W/cm}^3$
  - 4-filament 5-9s Al wire, 5-9s 51% cross-section and matrix low RRR
  - And AlBeMet AM162H
- YBCO has best metric  $< 87.1\text{K}$ ,  $< T_c$ 
  - YBCO coated-conductor still has ampacity above  $T_c$  but a positive offset versus pure stabilizer because the stabilizer is a fraction of the cross-section.
- Above 87.1K, AlBeMet AM162H has best metric
- 4-filament 5-9s Al wire is less competitive versus HTS at lower temperatures

# DC “Ampacity” of Cryoresistive and Superconducting Options

- Ampacity is a strong function available cooling
- This comparison is for:
  - High performance YBCO ( $I_c$  data for AP Superpower tape [<https://htsdb.wimbush.eu/>]) customized with a 20  $\mu\text{m}$  thick 500RRR Cu stabilizer and 30  $\mu\text{m}$  substrate.
  - $Q = 20 \text{ W/cm}^3$
  - 4-filament 5-9s Al wire, 5-9s 51% cross-section and matrix low RRR
  - And AlBeMet AM162H
- YBCO has best metric  $<81.3\text{K}, <T_c$ 
  - YBCO coated-conductor still has ampacity above  $T_c$ , but a positive offset versus pure stabilizer because the stabilizer is a fraction of the cross-section.
- Above 81.3K, AlBeMet AM162H has best metric
- 4-filament 5-9s Al wire is more competitive versus HTS at lower temperatures

# Cryoresistive DC Current Leads

- For high amperages, any current leads for cryo-power systems in the cryo → ambient (or higher T) transition will have substantial mass
- Standard techniques
  - Tapered leads, thin in cryo and thicker up top
  - Multi-cryoresistive material leads
  - HTS composite leads
- Minimize Joule Heating + Heat Leak
- First examining single material tapered leads

37 kA room temperature copper termination, 120 kg

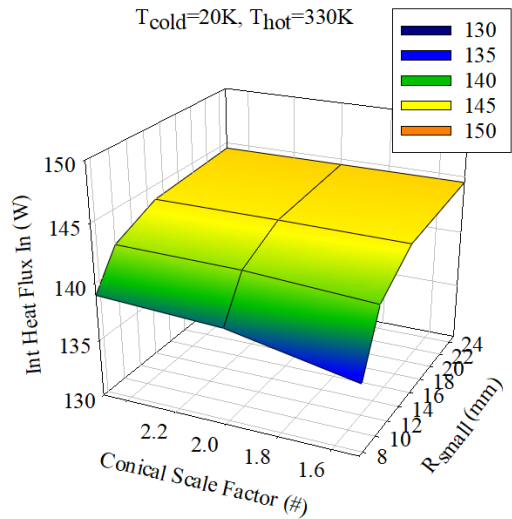

# Cryoresistive 3.3 kA DC Current Leads

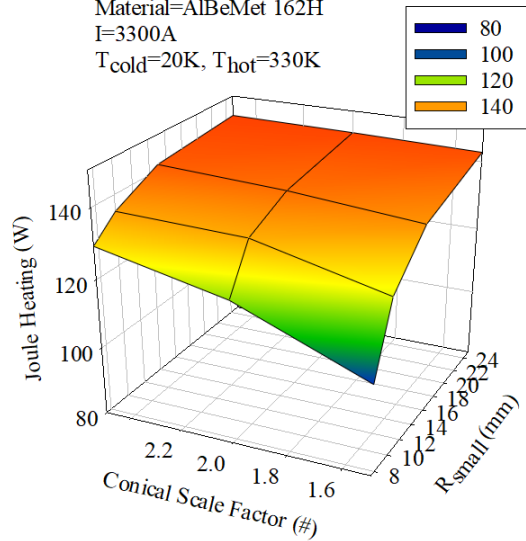

- HPAL(RRR=9000) and AlBeMet AM162H examined as a tapered single material current lead,  $k(T)$  and  $\rho(T)$
- Optimization to minimize incoming heat flux by changing length
- Parametric study of different conical scaling ratio, radii, and  $T_{cold}$  (20, 60, 77, and 112K)

Minimize Heat Flux into Cryogen  
Material=AlBeMet 162H  
I=3300A  
 $T_{cold}=20K, T_{hot}=330K$

Minimize Heat Flux into Cryogen  
Material=AlBeMet 162H  
I=3300A  
 $T_{cold}=20K, T_{hot}=330K$

Minimize Heat Flux into Cryogen  
Material=AlBeMet 162H  
I=3300A  
 $T_{cold}=20K, T_{hot}=330K$

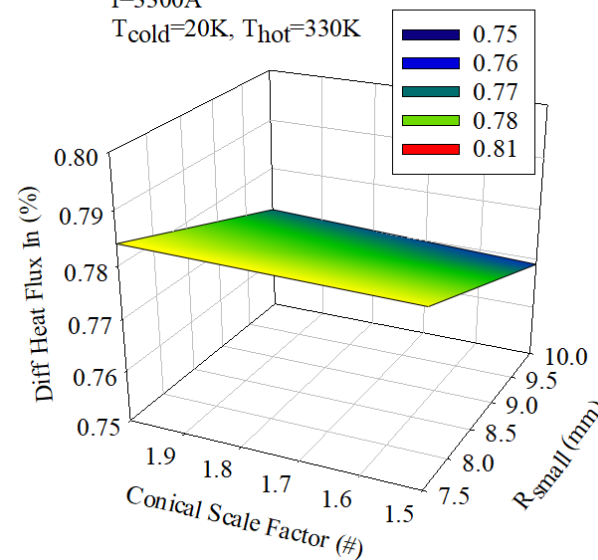

Minimize Heat Flux into Cryogen  
Material=AlBeMet 162H  
I=3300A  
 $T_{cold}=20K, T_{hot}=330K$

# Cryoresistive 3.3kA DC Current Leads Comparison

- AlBeMet 162H is substantially lower mass for low temperatures, but slightly higher heat flux in
  - For radii and scale factor examined
  - Lower electrical and thermal conductivity reduces length slightly to reach min heat flux
  - Density 2.1 g/cm<sup>3</sup> vs 2.7 g/cm<sup>3</sup>
- Need to examine different thermal gradients and consider incorporating into an HTS composite lead
- At 112K (LNG<sub>StdP</sub>) AlBeMet 162H is still lower mass and higher heat flux in, but the difference is smaller
- AlBeMet 162H is substantially more expensive per kg than aluminum (~\$700/kg)
  - Critical components such as low heat leak current leads for space and suborbital vehicles an analysis is necessary.

Minimize Heat Flux into Cryogen  
Material=HPAL vs AlBeMet 162  
I=3300A  
T<sub>cold</sub>=20K, T<sub>hot</sub>=330K

Minimize Heat Flux into Cryogen

I=3300A  
T<sub>cold</sub>=112K, T<sub>hot</sub>=330K

# AlBeMet AM162H for Cryogenic Low AC-Loss Applications

- Litz cable of cryoresistive conductors (50 μm filament diameter)
- Comparison with low-loss BSCCO-2212 wire
- $Q = 1, 5, 20 \text{ W/cm}^3$ , Solve for safe sinusoidal frequency at different temperatures
- Higher frequency desired for many rotating machines
- Power loss for BSSCO-2212 composite

$$P_{Coupling+Eddy} = \left(\frac{r_f}{r_0}\right)^2 \left(\frac{\pi^2}{2} B_m f\right)^2 \left(\frac{L_p}{2\pi}\right)^2 \left(\frac{1}{\rho_{ms}} \frac{r_0^2 - r_f^2}{r_0^2 + r_f^2} + \frac{1}{\rho_{tf}} \frac{r_f^2 - r_c^2}{r_f^2} + \frac{1}{\rho_{mc}} \frac{r_c^2}{r_f^2}\right) + \frac{\left(\frac{\pi^2}{2} B_m f\right)^2}{4\rho_{ms}} \left(\frac{r_0^4 - r_f^4}{r_0^2}\right)$$

$$P_{Hysteresis} = \left(\frac{8}{3\pi}\right) f \lambda B_m J_c d \left[1 + \frac{1}{3} \left(\frac{J_m}{J_c}\right)^2\right]$$

- Where “f”=AC frequency, “B<sub>m</sub>”=AC field magnitude, “λ”=SC%, “d”=filament diameter, “J<sub>m</sub>”=AC J magnitude, “r<sub>xxx</sub>” = different radii within of composite, “ρ<sub>xxx</sub>” = different resistivities within composite, and L<sub>p</sub> = twist pitch of superconducting filaments

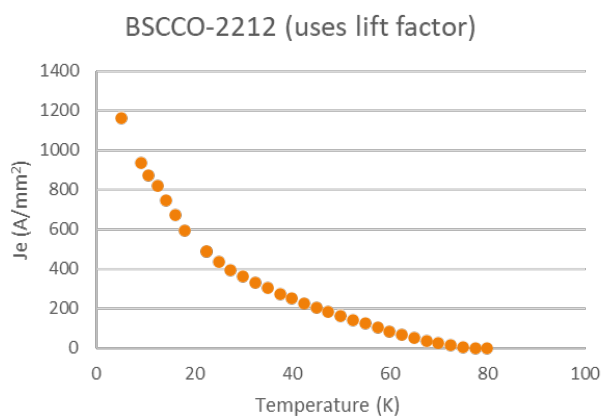

- Power loss calculated for Cryoconductor Litz

$$P_{Litz} [W/m^3] = J_{eng} BSSCO^2 \times \rho_{elec} + \frac{\pi^2}{4 \times \rho_{elec}} (B_m f d_f)^2$$

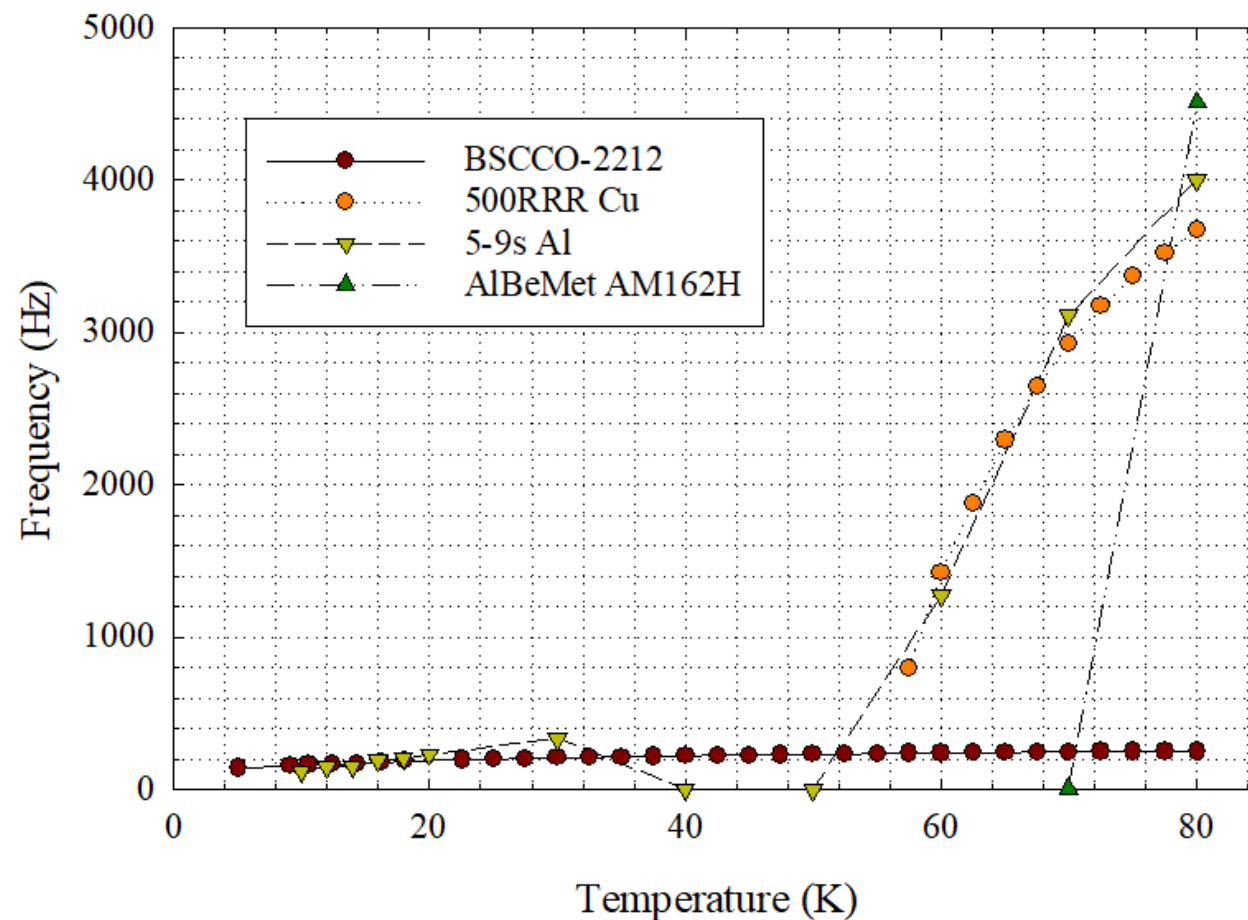

# Low AC Loss Cryoresistive versus SOA Bi-2212

- Frequency = 0 Hz when Ohmic losses from comparable BSCCO-2212  $J_e$  are higher than  $Q$
- AlBeMet AM162H can only compete versus BSCCO-2212 when  $J_e$  miniscule near  $T_c$
- 5-9s Al and Cu are both better options than BSCCO-2212 above 55K
- 5-9s Al is reentrant versus below 40K and surpasses BSCCO-2212 again near 30K

•  $Q = 10 \text{ W/cm}^3$

# Future Work

- Design, fabrication, and testing of optimized AlBeMet AM162H tapered current leads
- Brazing and crimp studies with AlBeMet AM162H leads to HPAL cable or solderable lugs
- Environmental coating for AlBeMet AM162H study
- Reachout/collaboration with Materion, NASA, others for studies

# Thank You CEC-ICMC 2023!

“Hawaii is one of those places that keeps topping itself. Just when you think you’ll never see another sunset as beautiful, there comes a sunrise that only Gauguin could imagine.”

-Thomas Sullivan Magnum IV  
(1982)
