Method Comparison for Calculating Properties of Charged Ferroelectric Domain Walls

Wednesday 21 June 2023 11:15 (15 minutes)

We consider two approaches when calculating the properties of a ferroelectric system with charged domain walls. These properties include domain wall width, electronic band structure and occupancy, and the electronic potential energy. Previously, a single parameter, Q, was argued to determine the crossover of the electron gas from quantum to quasi-classical. However, to obtain this result, two simplifying approximations were made in the description of the domain wall. When compared with a more robust approach it appears these approximations are only valid for a low Q value system. We discuss why these approximations are not always valid depending on the material parameters, i.e. the Landau theory parameters.
