

The Imaging X-ray Polarimetry Explorer (IXPE) and new directions for the future

Paolo Soffitta
IXPE Italian PI
(INAF-IAPS)

Advances in Space AstroParticle Physics
19-23 June 2023 Perugia (IT)

POLARIZATION FROM CELESTIAL SOURCES MAY DERIVE FROM:

- **Emission processes themselves:
cyclotron, synchrotron, non-thermal bremsstrahlung**

(Westfold, 1959; Gnedin & Sunyaev, 1974; Rees, 1975)

- **Scattering on aspherical accreting plasmas:
disks, blobs, columns.**

(1975; Sunyaev & Titarchuk, 1985; Mészáros, P. et al. 1988)

- **Vacuum polarization and birefringence through extreme
magnetic fields**

(Gnedin et al., 1978; Ventura, 1979; Mészáros & Ventura, 1979)

Fit function: $\mathcal{M}(\phi) = A + B \cos^2(\phi - \phi_0)$

Modulation: $\frac{\mathcal{M}_{\max} - \mathcal{M}_{\min}}{\mathcal{M}_{\max} + \mathcal{M}_{\min}} = \frac{B}{B + 2A}$

Polarization: $\frac{1}{\mu} \frac{B}{B + 2A}$ μ is the modulation factor, i.e. the modulation for 100% polarized radiation

Or by using Stokes Parameters

$$S(\varphi) = I + Q \sin(2\varphi) + U \cos(2\varphi)$$

$$I = \left(A + \frac{B}{2}\right) \quad U = \left(\frac{B}{2}\right) * \sin(2\varphi_0) \quad Q = \left(\frac{B}{2}\right) * \cos(2\varphi_0)$$

$$P = \frac{\sqrt{Q^2 + U^2}}{I} \quad \varphi = \frac{1}{2} \operatorname{atan} \frac{U}{Q}$$

Kislat et al. (2015) introduced the Stokes parameters from the direction of the single carrier of polarimetric observation

THE FIRST LIMIT: IN POLARIMETRY THE SENSITIVITY IS A MATTER OF PHOTONS

$$MDP = \frac{4.29}{\mu R_S} \sqrt{\frac{R_S + R_B}{T}} \quad \text{Minimum Detectable Polarization (MDP)}$$

R_S is the Source rate, R_B is the Background rate, T is the observing time
 μ is the modulation factor: the response of the polarimeter to a 100% polarized beam
 (spanning from 0 or no sensitivity, to 1 or maximum sensitivity)

If background is negligible: $MDP = \frac{4.29}{\mu \sqrt{N_{ph}}}$

To reach $MDP=1\%$ with $\mu=0.5$: $N_{ph} = \left(\frac{4.29}{\mu MDP} \right)^2 = 736 \cdot 10^3 \text{ ph}$

Source detection > 10 counts

Source spectral slope > 100 counts

Source polarization > 100.000 counts

Caution: the MDP describes the capability of rejecting the null hypothesis (no polarization) at 99% confidence. For a 3-sigma measurement an observing time 2.2 times longer is needed while the 1-sigma error scales like : $28^\circ.5/S/N$

LAUNCH (DECEMBER 9, 2021)

**Equatorial Orbit
600 km altitude**

RELEASE FROM THE FALCON 9

Optics Production Process

Mandrel fabrication

1. Machine mandrel from aluminum bar

2. Coat mandrel with electroless nickel (Ni-P)

3. Diamond turn mandrel to sub-micron figure accuracy

4. Polish mandrel to 0.3-0.4 nm RMS

5. Conduct metrology on the mandrel

Mirror-shell forming

6. Passivate mandrel surface to reduce shell adhesion

7. Electroform Nickel/Cobalt shell onto mandrel

8. Separate shell from mandrel in chilled water

Ni/Co electroformed IXPE mirror shell

MIRROR MODULE ASSEMBLY PROPERTIES

Property	Value
Number of modules	3
Mirror shells per module	24
Inner, outer shell diameter	162, 272 mm
Total shell length	600 mm
Inner, outer shell thickness	180, 250 μm
Shell material	Nickel cobalt alloy
Effective area per module	163 cm^2 (2.3 keV) ~ 192 cm^2 (3-6 keV)
Angular resolution	< 30 arcsec HPD
Detector limited FOV	12.9 arcmin
Focal length	4 m
Mass (3 assemblies)	93.12 kg

21/06/2023

ANGULAR RESOLUTION

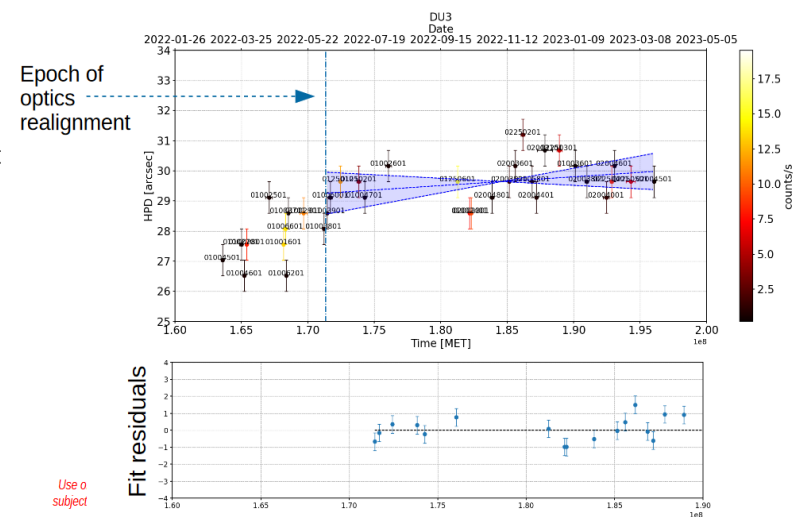

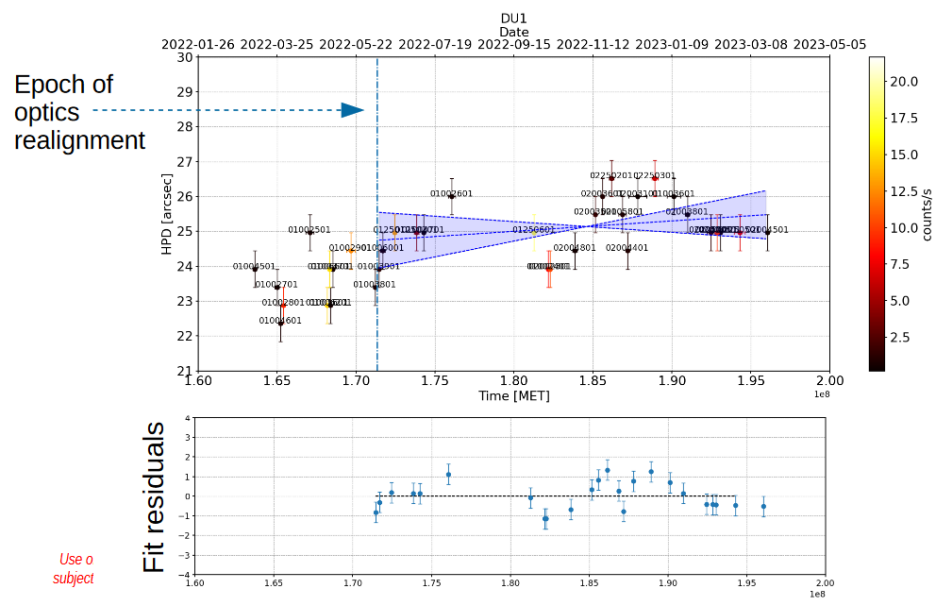

MMA	#1	#2	#3
6.4 keV	18.9"	24.8"	24.2"
4.5 keV	18.9"	25.0"	26.9"
2.3 keV	18.7"	24.5"	26.7"

Values in the table are half-power diameters (HPDs) for the individual MMAs alone. These need to be adjusted for alignment errors, detector resolution, focus etc. to determine the on-orbit system-level resolution.

Based upon X-ray calibration, analysis, and on-orbit performance the system-level performance is = 30" HPD

HPD MEASURED IN-FLIGHT

The inflight performance of the detector + mirror systems are in line with the expectation. The HEW is indeed dominated by the quality of the optics, then to the inclined penetration effects finally much less by the position resolution of the detector

PHOTOELECTRIC EFFECT TO MEASURE POLARIZATION OF X-RAYS

Proposed missions to date

Linear Polarization, Image, Energy, Time

Real modulation curve derived from the measurement of the emission direction of the photoelectron.

Position resolution < 120 μm (HEW)

Energy, space and time
resolved X-ray polarimetry

Energy resolution as function of energy

INFN-TEAM ASSEMBLY OF THE DUs

- DU mechanical housing design and procurement.
- DU thermal design and parts procurement
- Stray-light collimator design & procurement
- DU alignment system (collab. with MSFC & Ball & INAF)
- BEE electronics design and procurement
- BEE DAQ firmware, BEE software
- BEE Test

4 Flight Detector Units - AIVT (including environmental tests)
 1 Engineering Model DU (for BEE performance development)
 2 Qualification Model DU (Thermal and Structural models)

INAF CALIBRATION OF 3 FLIGHT DUS + 1 SPARE, AIV&T

- Calibration of DU have been carried out in Italy at INAF-IAPS, before Instrument integration and delivery to USA
- 40 days for each DU (3 flight + 1 spare units)
 - Up to 24/7 data acquisition
- First unit started calibration on 26th July, DU-FM2 started on 6th Sep 2019, DU3 on 23 Oct. 2019, DU 4 on 16 Dec. 2019
- 60% of time dedicated to characterization of the response to unpolarized radiation at 6 energies
- 17.5% of time dedicated to measurements of modulation factor at 7 energies
- Remaining time to calibrate other parameters of interest
- Energy calibration and dead-time are by-product of previous measurements

FILTER Calibration Wheel Assembly (In-flight calibration)

Flight Polarized X-ray sources

Ferrazzoli et al., 2020

^{55}Fe -powered calibration sources:

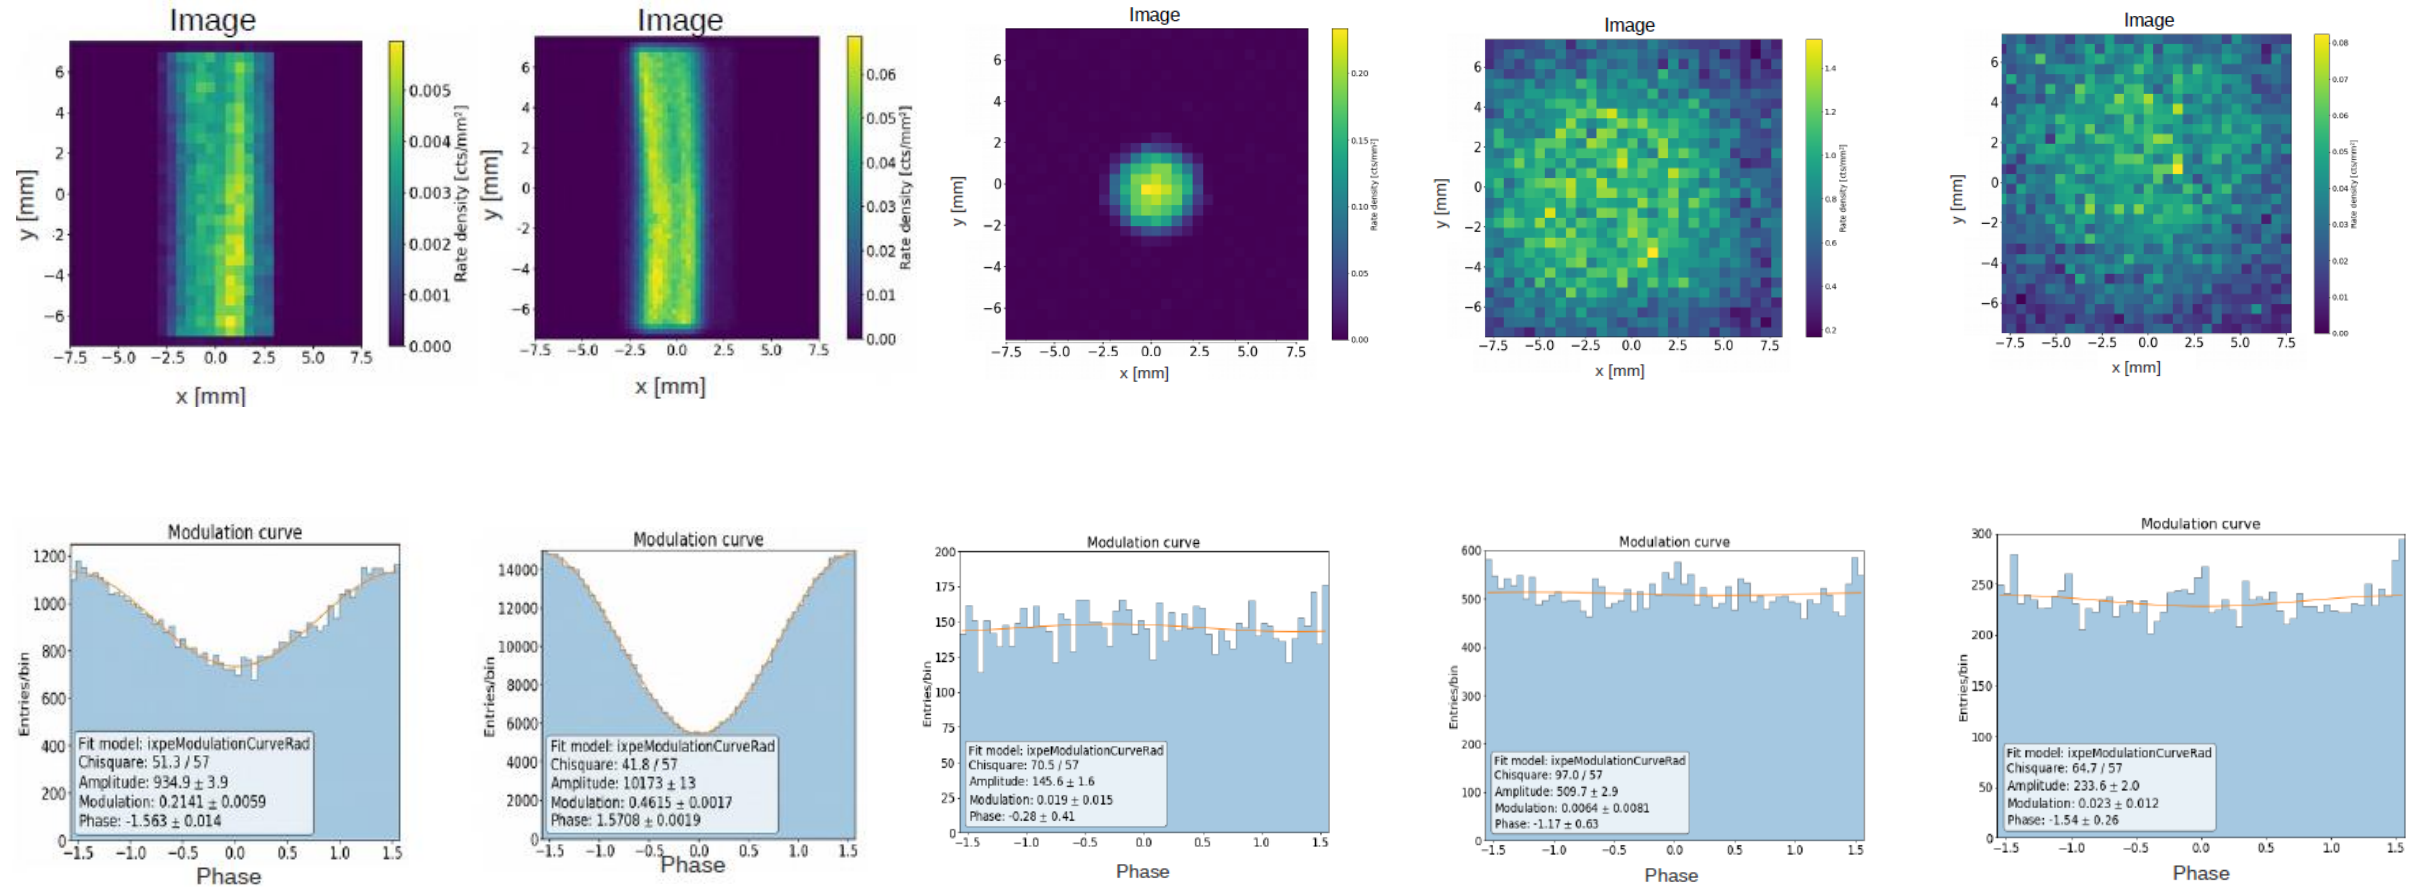

Cal A – Bragg-reflected polarized 2.98-keV ($\text{Ag-L}\alpha$ fluorescence) and 5.89-keV ($\text{Mn-K}\alpha$)

Cal B – unpolarized 5.89-keV spot

Cal C – unpolarized 5.89-keV flood

Cal D – unpolarized 1.74-keV ($\text{Si-K}\alpha$ fluorescence) flood

IMAGES AND MODULATION FACTORS OF THE CALIBRATION SOURCES

3.0 keV Cal A Pol

5.9 keV Cal A Pol

5.9 keV Cal B

5.9 keV Cal C

1.7 keV Cal D

Parameter	Value
Sensitive area	15 mm x 15 mm (13 x 13 arcmin)
Fill gas and composition	DME @ 0.8 atmosphere
Detector window	50- μ m thick beryllium
Absorption and drift region depth	10 mm
GEM (gas electron multiplier)	copper-plated 50- μ m liquid-crystal polymer
GEM hole pitch	50 μ m triangular lattice
Number ASIC readout pixels	300 x 352
ASIC pixelated anode	Hexagonal @ 50- μ m pitch
Spatial resolution (FWHM)	< 123 μ m (6.3 arcsec) @ 2 keV
Energy resolution (FWHM)	1.0 keV @ 6.4 keV (scaling as \sqrt{E})
Useful energy range	2–8 keV

MODULATION FACTOR (FROM CALIBRATION)

RESPONSE (3 POLARIMETERS)

Dithering has three selectable radius

- (small) 0.8 arcmin
- (medium) 1.6 arcmin periods in few hundreds s range
- (large) 2.6 arcmin

$$x = A \cdot \cos(wa \cdot t + \phi_iA) \cdot \cos(wx \cdot t + \phi_iX)$$

$$y = B \cdot \sin(wa \cdot t + \phi_iB) \cdot \sin(wy \cdot t + \phi_iY)$$

Given the lack of useful rotation a dithering is required to average out the systematic effects (Spurious Modulation) and to facilitate the ground calibration

Science Advisory Team (chaired by Giorgio Matt and Roger Romani)
Coordinates science activities required for planning, analyzing, interpreting, and reporting IXPE observations
Organized into seven Topical Working Groups

- *TWG1 Pulsar Wind Nebulae, led by Niccolò Bucciantini (INAF-Arcetri)*
Obtain polarimetric imaging to constrain the magnetic-field geometry of the nebula and the phase-dependent polarization of the pulsar
- *TWG2 Supernova Remnants, led by Pat Slane (CfA)*
Obtain spectral polarimetric imaging of Supernova Remnants (SNR) to constrain the magnetic-field structure of the X-ray emitting regions
- *TWG3 Accreting Black Holes, led by Michal Dovčiak (CAS-ASU)*
Obtain spectral polarimetry of microquasars to constrain the value of the black-hole spin parameter (if in soft state), or constrain the geometry of the corona (if in hard state)
- *TWG4 Accreting Neutron Stars, led by Juri Poutanen (Turku)*
Obtain phase-dependent polarimetry of accreting X-ray pulsars (high-magnetic-field binaries) to constrain models and geometries for the pulsing emission. Obtain polarimetry of non pulsating accreting NS to constrain the geometry of the system
- *TWG5 Magnetars, led by Roberto Turolla (Uni Padua)*
Obtain phase-dependent polarimetry of magnetars to constrain the effects of vacuum polarization (birefringence in a strong magnetic field)
- *TWG6 Radio-Quiet AGN & Sgr A, led by Frédéric Marin (Strasbourg)*
Obtain polarimetry of RQ AGN to constrain the geometry of the emitting regions
- *TWG7 Blazars & Radio Galaxies, led by Alan Marscher (Boston U)*
Obtain polarimetry of Blazars and RG to study jet emission

SOME RESULTS FROM IXPE CHANGED THE GAME

(Xie et al., 2022)

Vela PWN showed a polarization close to the synchrotron limit

(Doroshenko et al., 2022)

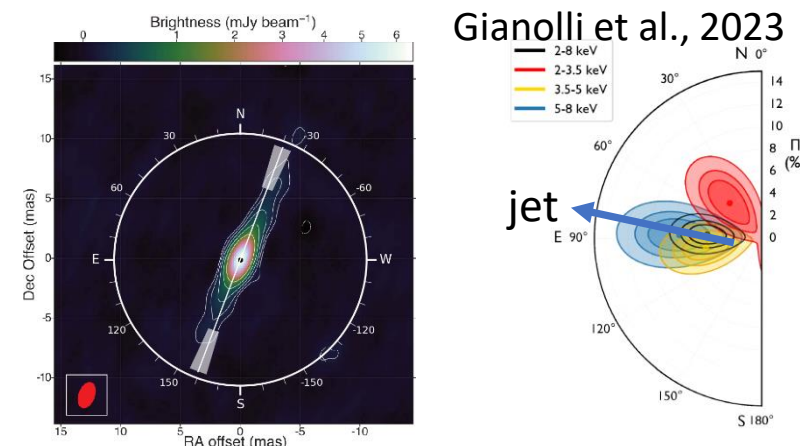

X-ray binary pulsars much less polarized than expected.

Krawczynski et al., 2022

Polarization in Cyg X-1 larger than expected. Sandwich corona for both Cyg X-1 and NGC 4151

Gianolli et al., 2023

NGC 4151

Taverna et al. 2022

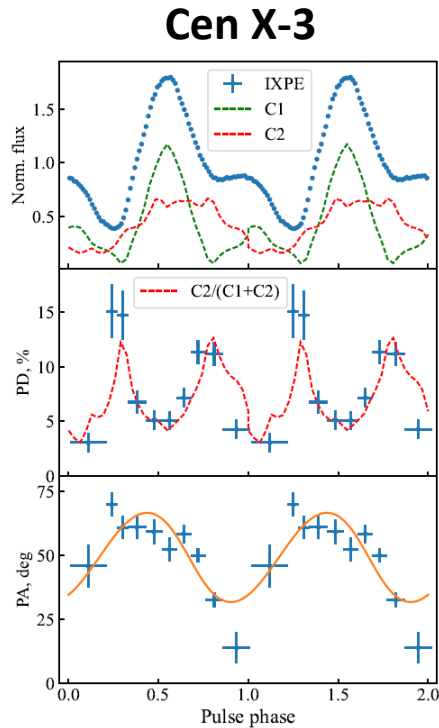

Zane et al. 2023

Two magnetars: two different behaviors of energy-resolved polarimetry challenge models

CEN X-3 AND HER X-1 DISENTANGLING THE GEOMETRY

Tsygankov et al 2022

Fig. 4 | Geometry of the system from the observer's perspective. The grey plane is the plane of the sky, labelled with north and east axes, perpendicular to the line of sight towards the observer \hat{o} . The angles between the line of sight and the vectors of the pulsar spin $\hat{\Omega}_p$ and the orbital angular momentum $\hat{\Omega}_{orb}$ are the inclinations i_{orb} and i_p . The corresponding position angles χ_p and χ_{orb} are the azimuthal angles of the spin vectors projected onto the sky, measured from north to east. The misalignment angle β is defined as the angle between $\hat{\Omega}_p$ and $\hat{\Omega}_{orb}$. The magnetic obliquity θ is the angle between magnetic dipole and the rotational axis.

Doroshenko et al., 2022

Rotating Vector Model

Magnetic obliquity	$\Theta = 16.4(\pm 1.3)^\circ$
Inclination	$i_p = 70^\circ.2$
Position angle	$\chi_p = (49.2 \pm 1.1)^\circ$

Table 1 | Orbital and pulsar geometrical parameters of Her X-1

$\chi_{p,*}$	θ	i_p	$\chi_{orb,*}$	i_{orb}
deg	deg	deg	deg	deg
56.9 ± 1.6	12.1 ± 3.7	Eq. (2)	28.9 ± 5.9	100.4 ± 4.9

SuperNova Remnants

Allen '97

Bleeker 2001

Rotating each photon with respect to the center and selecting the energy range between the calcium line and the Iron line we demonstrated that, as in radio, the polarization angle is perpendicular to the radius of the SNR as in radio band (*Vink et al. 2022*)

Polarization of the non-thermal emission is low (2-5 %) similar to radio.
 Both radio and X-rays point to radial magnetic field → Turbulent magnetic field realignment close to the shock.

Qualitatively similar results for Tycho (i.e. radial magnetic field), but with larger polarization degrees, up to 23 ± 4 % in the west region (*Ferrazzoli et al. 2023*)

→ Less turbulent magnetic field (or a larger maximum turbulence scale)

Type Ia, AD 1572

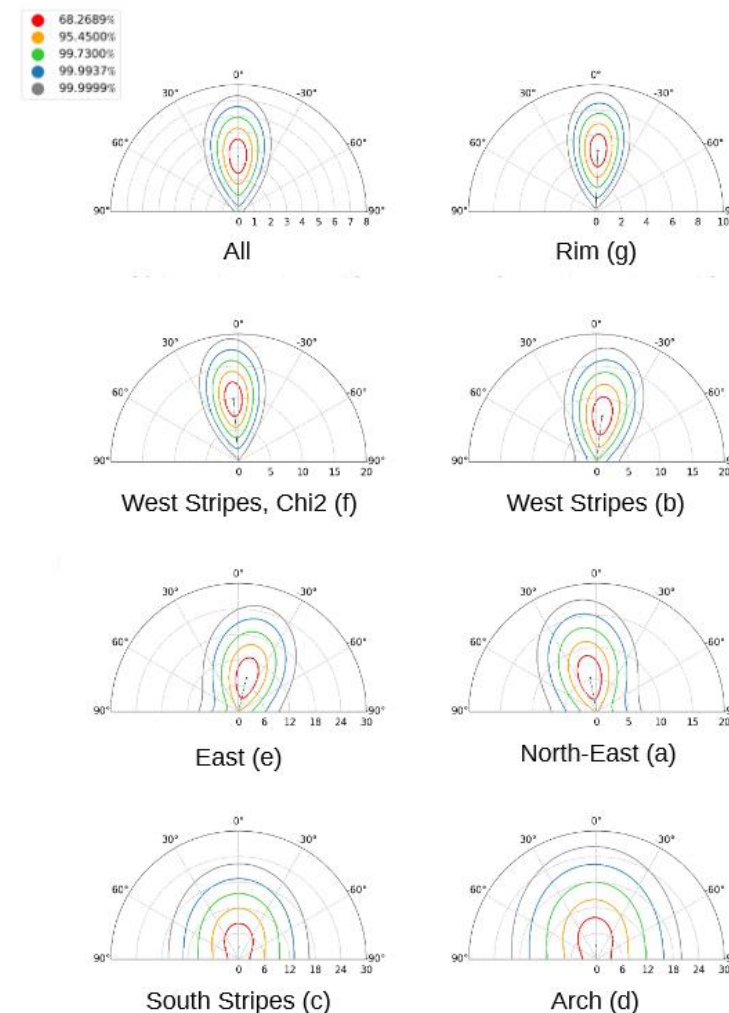

Figure 2. IXPE three color image of Tycho combined from the three detectors based on the 2–3 keV (red), 3–4 keV (green), and 4–6 keV (blue) bands. Superimposed are the regions considered in this work: the northeast (a), the west stripes (b), the south stripes (c), and the Arch (d) are the ones identified by *Eriksen et al. (2011)*. The regions (e) and (f) are, respectively, the east knot and the west region where strong X-ray polarization is detected. Finally the region (g) identifies the rim and the entire SNR.

FROM POLARIMETRY OF MOLECULAR CLOUDS IN THE GALACTIC CENTER REGION TO ROTATING POLARIZATION IN BLAZARS

Molecular clouds are cold clouds emitting X-rays.

Possibly they are reflecting emission from the past from Sgr A*

21/06/2023

Marin et al., Nature 2023

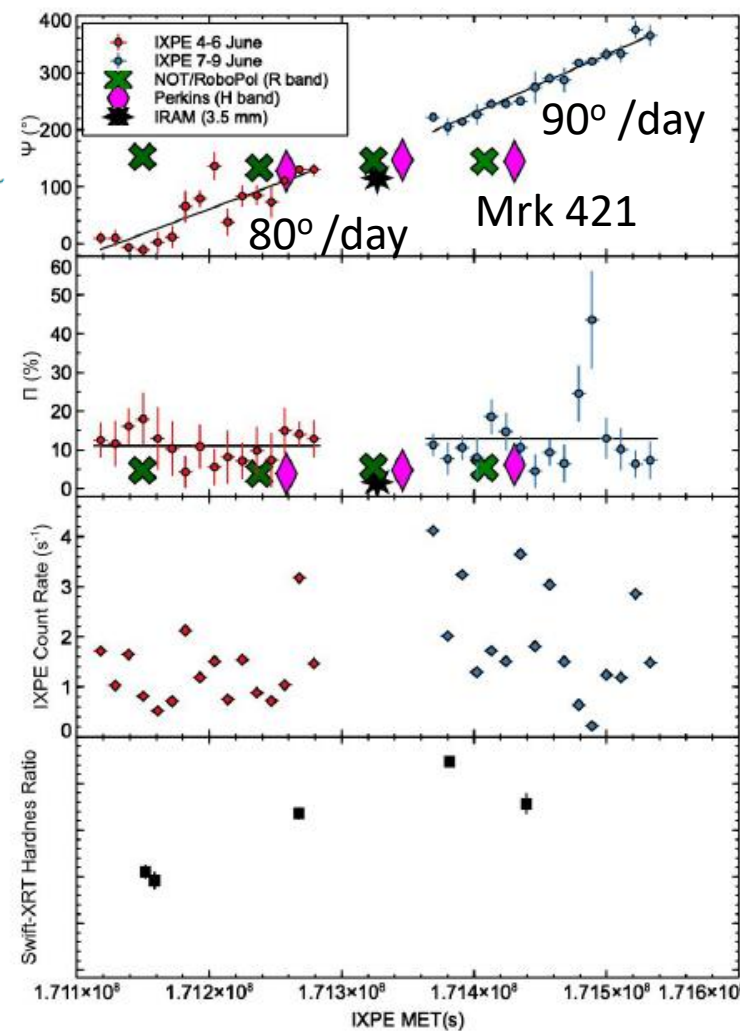

Radio Galaxies with relativistic jets directed toward us are called Blazars

IXPE detected for the first time a rotation of the polarization angle with time. An helical magnetic field.

No rotation at longer wavelength

Particle Physics, 19-23 June 2023, Perugia (It)

Di Gesu et al., Nature Astronomy

2-D round track image: emission direction or scattering ?

Costa et al., 2001

Ambiguity: is the 2-D image of a track round

- (1) Because of the scattering Rutherford ?
- (2) Because it is ejected perpendicularly to the readout plane ?

Photoelectron track ejected parallel to the X-Y plane

Track either randomized or ejected along Z

TimePIX3: from MEDIPIX CERN collaboration

Timepix3: a 65K channel hybrid pixel readout chip with simultaneous ToA/ToT and sparse readout

Parameter	Value
Pixel matrix	256 x 256 = 65536 pixels (2x4 superpixels)
Pixel size	55 x 55 μm^2
Technology	CMOS 120 nm
Measurement type	<ol style="list-style-type: none"> 1. Simultaneous 10 bit TOT, 14 + 4 bit ToA 2. 14 + 4 bit ToA only 3. 14 bit integral ToT
Readout type	<ol style="list-style-type: none"> 1. Data Driven (zero-suppression) 2. Frame based (zero-suppression)
Dead time per pixel	ToT + 457 ns (pulse processing + data transfer)
Output bandwidth	Up to 5.12 Gbs (parallel 8 channels x 640 Mbps)
Maximum Counting rate	Data Driven up to 40Mhits/cm ² /s with duty cycle of 100 %
TOA precision (resolution)	1.56ns
Front End noise, minimum threshold	60 e _{rms} , 500 e ⁻

Kaminski, 2017, Lupberger 2015

Ongoing collaboration with University of Bonn

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

Wider energy band & imaging for Supernova Remnants

Rotating each photon with respect to the center and selecting the energy range between the calcium line and the Iron line we demonstrated that, as in radio, the polarization angle is perpendicular to the radius of the SNR (*Vink et al. 2022*)

Imaging polarimetry beyond 6.4 keV will measure polarization directly of the non-thermal emission due to synchrotron

10 m focal length will impose multiple observations for Tycho Supernova a single observation for Cas A

A wide field/collimated experiment of X-ray polarimetry requires a large area

Li, 2021

Feng et al., 2019

An alternative approach

- Background Polar Light : about 80 mCrab after discrimination, (Jiahuan Zhu 2021)
- Collimator open fraction 71 %
- Area 1000 cm²
- Crab rate = 65 c/s (2-8 keV)
- Background = 5 c/s
- MDP (1 Crab 100 000 s) = 0.5 %

512x448 pixels (55x55 μm²)

Area 1 ASIC 7 cm²

Tiling on 4 Sides

200 ps time resolution

140 ASICs to cover 1000 cm²

Large power required

Llopart et al., 2022

Timepix4v0 with 4x300 μm (256x256) edgeless Si sensor (August 2020)

Optical photoelectron track imaging
(see the talk by Elisabetta Baracchini)

Baracchini et al., 2020, Amaro et al., 2022

Possible future photoelectric X-ray polarimetry experiments

Imaging wide energy range (ESA or NASA)

- **2-10 keV band: focal plane with large throughput conventional X-ray optics (3.5-4 meters Focal Length)**
 - DME or low diffusion mixtures
 - Scientific objectives: all the IXPE ones but with a much larger sensitivity. Possibly add GRB afterglow and tidal disruption events if rapid repointing is available
 - Possible missions: eXTP (ESA-CAS), NGXM (ESA), XPP (NASA)
- **6-35 keV band: focal plane (photoelectric) and 20-80 segmented Compton polarimetry: multilayer optics: (10 m focal length)**
 - Pressurized Ar-DME or Ar-CO₂
 - Additional Scientific objectives:
 - Cyclotron lines
 - Hard tails of Magnetars
 - Reflections in Binaries and AGNs
 - Reflection Nebulae
 - Possible missions NGXM (ESA), XPP (NASA)

Non imaging

- **Collimated narrow field experiment: Photoelectric effect (2-10 keV) or (6-35 keV)**
 - Bright Galactic sources > 100 mCrab
 - Already observed by IXPE but interesting for monitoring
- **Wide field experiment (Photoelectric: charge or optical readout (see talk E. Baracchini))**
 - Broad collimator
 - Area >> 1000 cm²
 - Prompt GRB and X-ray transients studies (Magnetars, BH binaries)

High Energy Polarimeter (Scattering)

Medium Energy Polarimeter (Photoelectric)

Most of the cyclotron fundamental lines can be probed by photoelectric imaging Polarimeters (Pressurized Argon, Medium Energy). The higher energy end requires Active Compton scattering polarimeter

X-ray polarimetry in a wide energy band

(Soffitta et al., 2010)

Low Energy Polarimeter (photoelectric, LEP, 2-8 keV) configuration IXPE-like
 Medium Energy Polarimeter (photoelectric, MEP, 6-30 keV (3 bar Ar-DME 80-20 Mixture)
 High Energy Polarimeter (Compton: segmented scatterer or single scatterer HEP, 20-80 keV)

The quality factor of the three polarimeters is well matched providing similar sensitivity at the focus of a multi-layer optics

Collaboration with University of Bonn for GridPIX detector

X-ray polarimetry in a wide energy band

Tagliaferri et al., 2010

Tagliaferri et al., 2010

One NHXM-type telescope provides the sensitivity of the three IXPE telescopes

NGXM-New generation X-ray Mission

- White paper ESA Voyage 2050
(Experimental Astronomy Soffitta et al., 2020)

XPP X-ray Polarization Probe

- White paper 2020 Decadal Survey
(Yahoda et al., 2019)

Ongoing experiments:

Fine Imaging telescopes: (2-8 keV) & (6-35 keV)

Hard X-ray imaging polarimeter (20-80 keV)

Non Imaging TPC-like experiment

Wide Field Polarimeter and Imager

- Stacked TPC (non-imaging)+ Passive Compton polarimeter
- Low energy (multilayer) polarimeter
- Imaging polarimeter

XL-Calibur (high background passive scatterer 10 m FL)

BACKGROUND REJECTION AND SUBTRACTION

Di Marco et al., 2023 AJ accepted

Background counting rate $0.003 \text{ c/s /arcmin}^2$

- *Bright source* counting rate $> 2 \text{ c/s /arcmin}^2$ ($\sim 15 \text{ mCrab}$)
No Rejection and No Subtraction to be applied to the data
- *Faint Sources* counting rate $< 1 \text{ c/s /arcmin}^2$ ($\sim 7.5 \text{ mCrab}$)
Either Rejection and Subtraction to be applied to the data
- *Intermediate source*
Rejection to be applied No subtraction unless background template

In the current pipeline *background rejection* is not applied. Needed Level 1 data
Background subtraction can be performed on Level 2 data as for any X-ray imaging satellite

Photoelectric polarimetry for HETE-2 GRB

A wide field polarimeter with 1000 cm^2

DME 1 Atm 4 cm deph

We did not plan to follow-up on GRBs, because of the relatively slow reaction time (2-3 days).

However, GRB 221009A (the 'BOAT' GRB) was so exceptional in terms of brightness, that we decided to observe it.

Swift/XRT image

$P < 13.8\%$ (99% c.l.)

(Negro et al. 2023)

Dust rings also observed →
polarization of the prompt emission (<55%)

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

Weisskopf et al., 2022

Energy resolution

The energy resolution is already better than that the typical proportional counter

Kaminski 2017

An energy resolution down to 10 % can be reached with GridPIX technologies at 6 keV

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

Wide energy band and no imaging for Low Magnetized Neutron Stars

Farinelli et al., 2022

Capitanio et al., 2022

Comptonization extends up to 20-30 keV. It might be interesting to explore polarimetry in this energy band. It might help to constrain the geometry of the reflecting elements

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

IXPE energy band

Future Hard X-ray imaging polarimetry

Wider energy band & imaging for AGNs

Credit Ricci, C.

Polarimetry above 6 keV to study reflection phenomena suffers of both a small detector quantum efficiency/mirror effective area. Reflection phenomena are poorly constrained

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

Larger Effective area & better Point Spread Function

Larger mirror effective area

Larger detector Q.E. →
electro-negative mixtures

Better than 30' HEW

Two magnetars showed
different behavior with 1
Ms net observing time
(20 days each). Needed a
large area to improve the
sensitivity.

36 % MDP on the jet (100 ks)

Ehlert et al., 2022

Ferrazzoli et
al., 2023

Few pixels showed
significant polarimetry

MRK 501

Mrk 501 HBL Blazar
Peak @ $2.8 \cdot 10^{15}$ Hz

γ -ray > 0.1 TeV

IXPE observed Mrk 501
at an average X-ray flux.

**Observed three times
for total 300**

Model	Mltiwavelength polatization	X-ray polarization variability	X-ray polarization angle
Single-zone	Constant	Few-days/week	any
Multi-zone	Mildly chromatic	Less of 1 day	any
Energy stratified (shock)	Strongly chromatic	Few-days/week	Along the jet axis
Magnetic reconnection (kink instability)	Constant	Moderate	Perpendiculat to the jet axis
IXPE Finding	Strongly chomatic	Few-days/week	Along the jet axis

- Shock acceleration: the higher energy particles probe more magnetically ordered regions closer to the shock
- Downstream of the shock the magnetic field becomes more turbulent were less energetic photons are emitted

A ROTATION OF THE POLARIZATION ANGLE IS DETECTED IN X-RAYS

- During X-ray rotation millimeter-wave, infrared and optical polarization angle didn't vary substantially.
- Rotation in optical light is few-few tens of degree/day
- PD_X was roughly constant and higher wrt Optical, Infrared and Radio
- At GeV was in a quiescent state

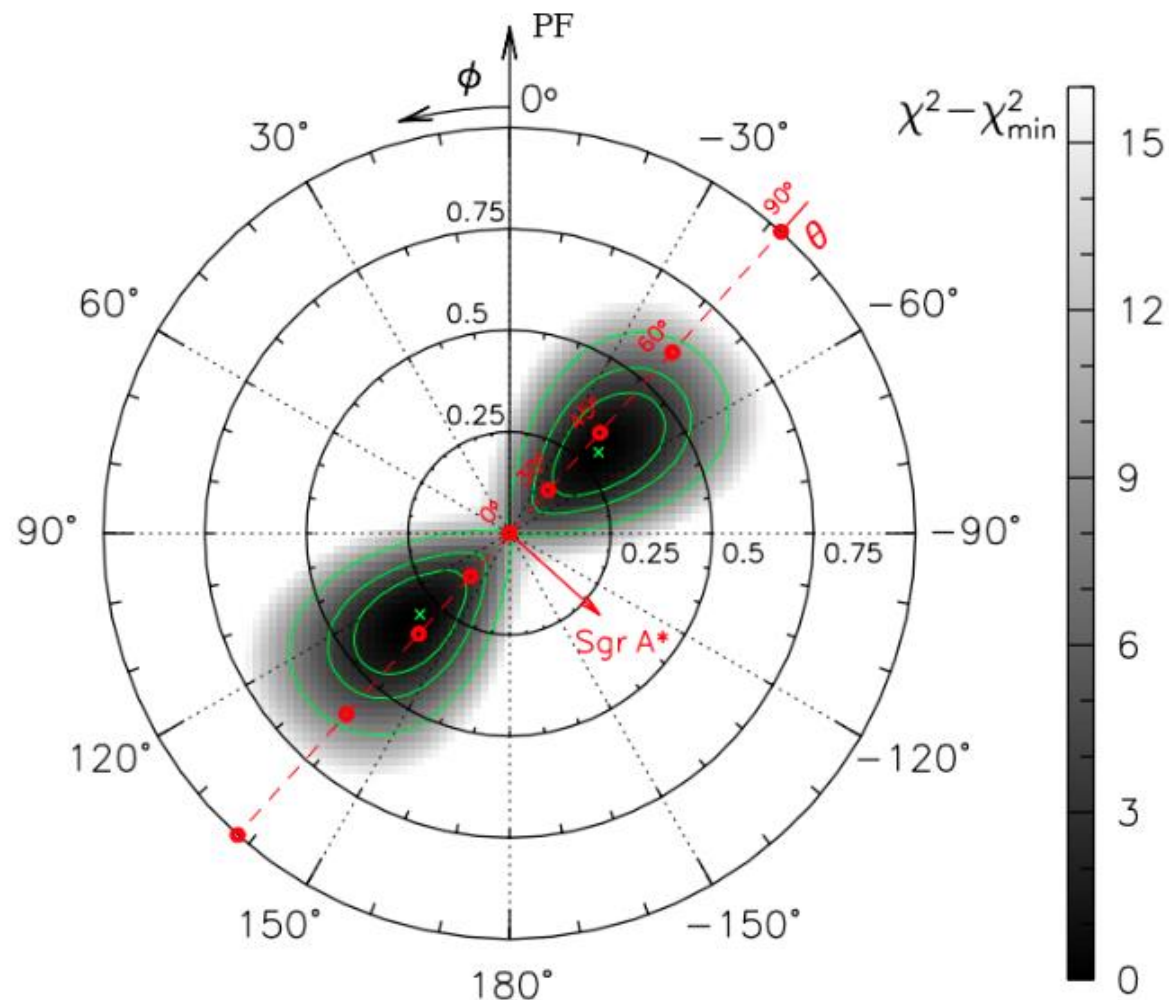

Fig. 2 Sketches of the scenario proposed to explain the X-ray polarization angle rotation in Mrk 421. Left: an off axis emission feature, e.g., a magnetosonic shock, propagates along helical magnetic field lines down the jet. Right: the appearance of the emission feature, magnetic field, and polarization vector at 4 azimuthal positions along its spiral path as viewed by a distant observer aligned with the jet. The red circle represents the emission feature, while the blue-shaded region is the ambient jet.

Di Gesu, Nature Astronomy in press

- **OBJECTIVE 1: Active Galactic Nuclei (AGN)**
 - Obtain polarimetry of RQ AGN to constrain the geometry of the emitting regions, and of Blazars and RG to study jet emission
- **OBJECTIVE 2: Microquasars**
 - Obtain spectral polarimetry of microquasars to constrain the value of the black-hole spin parameter (if in soft state), or constrain the geometry of the corona (if in hard state)
- **OBJECTIVE 3: Radio Pulsars and Pulsar-Wind Nebulae**
 - Obtain polarimetric imaging of the Crab to constrain the magnetic-field geometry of the nebula and the phase-dependent polarization of the pulsar
- **OBJECTIVE 4: Supernova Remnants**
 - Obtain spectral polarimetric imaging of Supernova Remnants (SNR) to constrain the magnetic-field structure of the X-ray emitting regions
- **OBJECTIVE 5: Magnetars**
 - Obtain phase-dependent polarimetry of magnetars to constrain the effects of vacuum polarization (birefringence in a strong magnetic field)
- **OBJECTIVE 6: Accreting Neutron Stars**
 - Obtain phase-dependent polarimetry of accreting X-ray pulsars (high-magnetic-field binaries) to constrain models and geometries for the pulsing emission.
Obtain polarimetry of non pulsating accreting NS to constrain the geometry of the system.

Was the galactic center active 200 years ago ?

2.8 σ result. Polarization angle consistent with Sgr A* as the origin of the illuminating radiation.

From the polarization degree, two solutions for the age of the burst: ~30 or ~200 years ago. Second solution much more probable a flare 30 years old should have been visible.

Beside a larger effective area and better HEW mirror

Determination of geometrical parameters

Table 1 | Orbital and pulsar geometrical parameters of Her X-1

$\chi_{p,*}$	θ	i_p	$\chi_{orb,*}$	i_{orb}
deg	deg	deg	deg	deg
56.9 ± 1.6	12.1 ± 3.7	Eq. (2)	28.9 ± 5.9	100.4 ± 4.9

$$\tan(\text{PA} - \chi_p) = \frac{-\sin \theta \sin(\phi - \phi_0)}{\sin i_p \cos \theta - \cos i_p \sin \theta \cos(\phi - \phi_0)}$$

As promised from the swing of the polarization angle is possible to derive geometrical properties: Projection of the spinning vector in the plane of the sky and the angle between the rotation axis and the dipole axis. These are usually free parameters in spectral fittings now they are directly measured by X-ray polarimetry

Fig. 4 | Geometry of the system from the observer's perspective. The grey plane is the plane of the sky, labelled with north and east axes, perpendicular to the line of sight towards the observer \hat{o} . The angles between the line of sight and the vectors of the pulsar spin $\hat{\Omega}_p$ and the orbital angular momentum $\hat{\Omega}_{orb}$ are the inclinations i_{orb} and i_p . The corresponding position angles χ_p and χ_{orb} are the azimuthal angles of the spin vectors projected onto the sky, measured from north to east. The misalignment angle β is defined as the angle between $\hat{\Omega}_p$ and $\hat{\Omega}_{orb}$. The magnetic obliquity θ is the angle between magnetic dipole and the rotational axis.

Improving and expanding the capabilities of X-ray Polarimetry beyond IXPE

Algorithms

$$\text{MDP}_{99} = 5.5 \% \sqrt{\frac{1}{\frac{T}{10 \text{ days}} * \frac{F}{0.5 \text{ mCrab}}}} \quad (2-8 \text{ keV}) \quad \text{Requirement}$$

- The mirror effective area after construction is about 20 % smaller than expected.
- The detector is about 20 % less efficient than expected (but larger modulation factor)

$$\text{MDP}_{99} = 6.2 \% \sqrt{\frac{1}{\frac{T}{10 \text{ days}} * \frac{F}{0.5 \text{ mCrab}}}}$$

$$\text{MDP}_{99} = 5.5 \% \sqrt{\frac{1}{\frac{T}{10 \text{ days}} * \frac{F}{0.5 \text{ mCrab}}}}$$

$$\text{MDP}_{99} = 5.0 \% \sqrt{\frac{1}{\frac{T}{10 \text{ days}} * \frac{F}{0.5 \text{ mCrab}}}}$$

Unweighted analysis

Weighted analysis

Di Marco et al., 2022 AJ

Convolutional Neural Network (Peirson& Romani, 2021 ApJ)

Visual Transformer & Graph Neural Network

Neural Networks seems promising techniques. They need to be validated with real calibration data because Monte Carlo training can hide a non uniform response to unpolarized radiation. Measuring flat response to unpolarized radiation is very difficult.

Pulsar Wind Nebulae

IXPE observations of PWN (Crab, Vela) confirmed they are highly polarized (very high in certain regions, close to the synchrotron limit) (*Bucciantini et al. 2023, Xie et al. 2022*).

Crab result consistent with OSO-8, when integrated over the entire nebula. However, polarization map shows a complex pattern, not surprisingly given the Chandra image

21/06/2023

Advances in S

Crab nebula and pulsar

OSO-8 and IXPE results

Fig. 4 | Polarized structure of the Crab nebula. The right panel shows the total intensity map of the Crab PWN + PSR complex in the [2–8] keV energy band, overlaid with the reconstructed polarization direction (magnetic field). The

left panel shows a map of the PD cut above 5σ confidence level. The grey dashed line is the nebular axis inferred from X-ray intensity maps³¹. Overlaid are the sky directions for ease of reference.

The overall polarization pattern confirms the expectation that synchrotron emission takes place in the (mostly) toroidal magnetic field.

There is a change in PA between the low [2-4] keV and high [4-8] keV energy band. (Same trend of OP)

The level of angular resolved polarization suggest that turbulence is not as strong as predicted

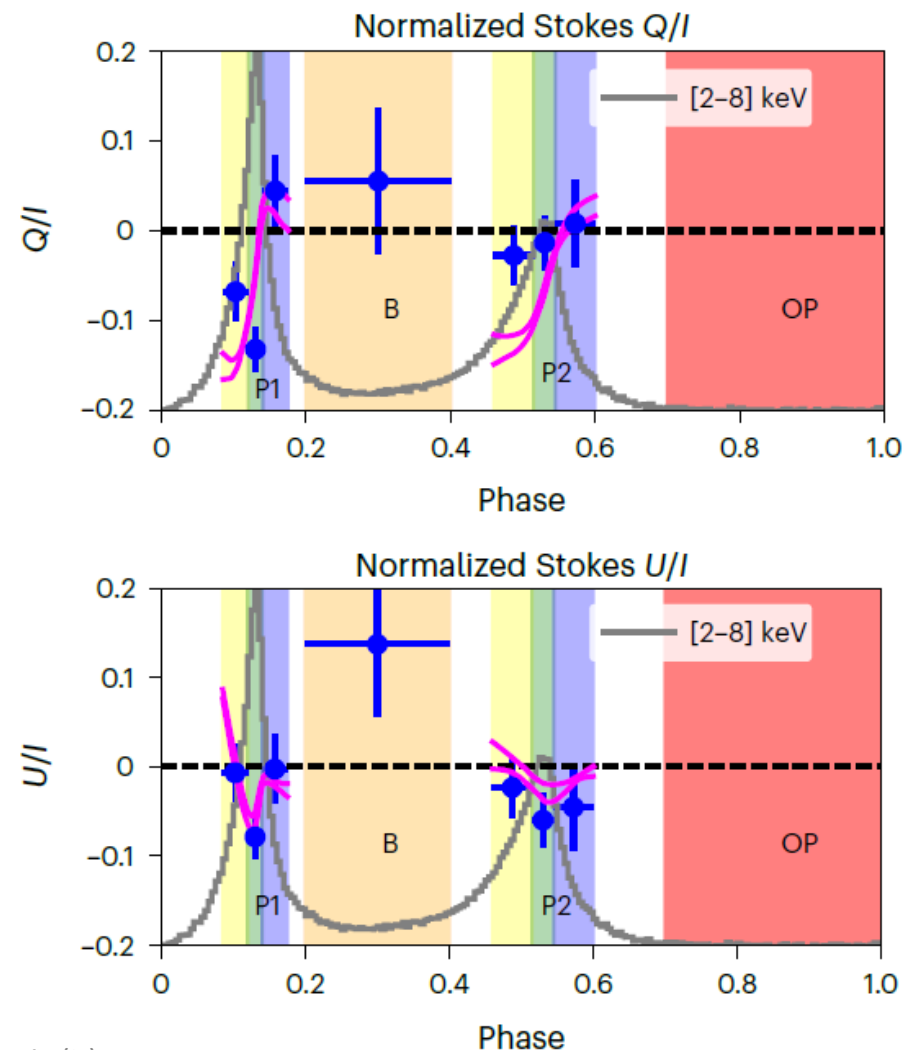

Crab Pulsar polarimetry

Polarization has been positively measured in the central bin (core) of the P1 pulse

$PD = 15.4 \pm 2.5\%$ $PA = 105 \pm 18^\circ$. There is no significant change of the polarization properties of this phase bin with energy.

Deviations with respect to the optical polarization are prominent for Q/I in the left wings of both P1 and P2. U/I on the other hand is in very good agreement.

A simple PA swing over P1 does not seem capable by itself of explaining the presence of a highly polarized core in P1 with low polarization wings unless the PA swings much faster in X-rays than in the optical range. Intrinsic depolarization is most required.

The Vela PWN

Average polarization of 45%, larger than 60% is some, small regions → close to the Synchrotron limit!

High polarization suggests B less turbulent than expected.

Polarization consistent with radio, but X-rays sample regions closer to the site of acceleration.

(Xie et al. 2022)

SuperNova Remnants

Rotating each photon with respect to the center and selecting the energy range between the calcium line and the Iron line we demonstrated that, as in radio, the polarization angle is perpendicular to the radius of the SNR as in radio band (*Vink et al. 2022*)

We measured X-ray polarization also from SN 1006 with magnetic field parallel to the shock normal. Polarization for non thermal emission is increasingly high for Cas A, Tycho and SN 1006.

■ Anomalous X-ray Pulsars and Soft-gamma ray repeaters

- $P \approx 2 - 12 \text{ s}$ $\dot{P} \approx 10^{-14} - 10^{-10} \text{ s s}^{-1}$
- $B_{sd} \approx 10^{14} - 10^{15} \text{ G}$
- $L_{X,persist} \approx 10^{35} - 10^{36} \text{ erg s}^{-1}$ (typically $> \dot{E}_{rot} = 10^{33} - 10^{34}$)
- Bursting activity (short bursts – intermediate/giant flares)
- Enhanced activity in transient sources (outbursts)
- Two components (thermal and PL) spectra
- **Powered by their own magnetic energy**

A twisted magnetic field is coupled to flowing charged particles which upscatters (power law) the radiation emitted from the neutron star surface (Thermal)

Magnetars: 4U 0142+61

Strong dependence on energy, suggesting a switch of the dominant mode from low to high energies (*Taverna et al. 2022*).

Polarization degree drops to
~ 0 at around 4 – 5 keV

Polarization angle swings
by 90°

Averaged PD = (13.5+/-0.8)%

	2-3 keV	3-4 keV	4-4.75 keV	4.75-5.5 keV	5.5-8 keV
PD (%)	16 ⁺² ₋₂	14 ⁺² ₋₂	6 ⁺⁵ ₋₅	10 ⁺⁸ ₋₈	35 ⁺¹¹ ₋₁₁
PA (deg)	47 ⁺³ ₋₃	53 ⁺⁴ ₋₄	41 ⁺²⁶ ₋₂₆	-64 ⁺²⁹ ₋₆₄	-39 ⁺⁹ ₋₉

Magnetars: 4U 0142+61

- Two spectral components differently polarized
- Polarization angle swing by 90°
- Modest low-energy polarization
- Phase-dependent behavior of Flux, PD and PA

Most likely interpretation

Thermal + Resonant Compton Scattering

Ordinary (Extraordinary) mode dominating at low (high) energies

Resonant Compton scattering produce X-mode polarization at high energies

Condensed surface is invoked for producing low energy O-mode

The atmosphere is condensed due to the high magnetic field: The atoms attain a cyclindrical structure and the elongated atoms form molecular chains by covalent bonding along the field direction.

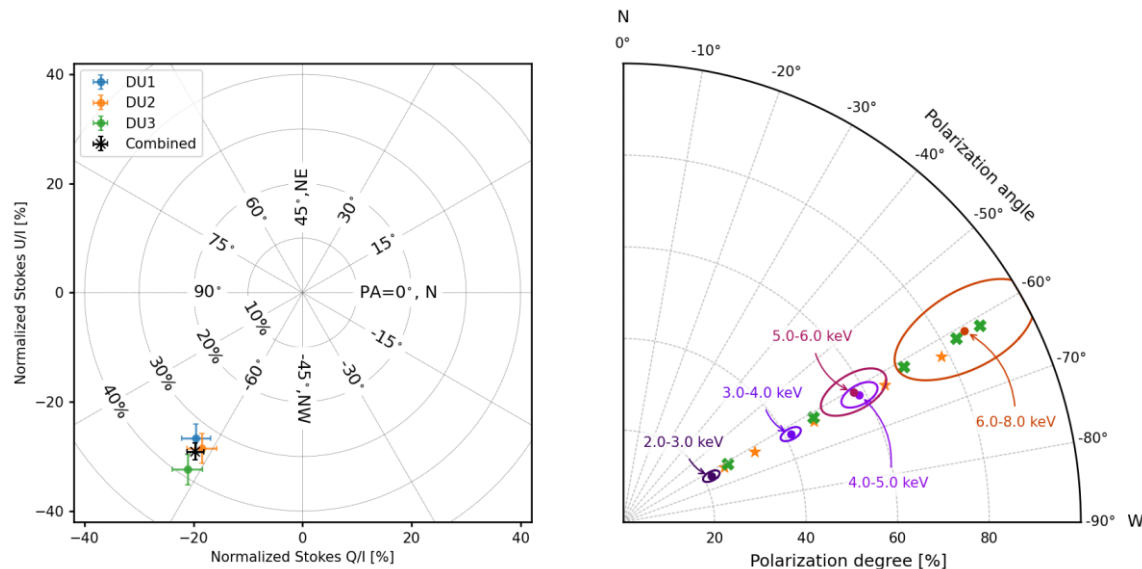

Consistent with Vacuum Birefringence expected in QED (but never verified experimentally)

Magnetars: J1RXS J170849.0-400910

A second magnetar (J1RXS J170849.0-400910) has then been observed.

Averaged PD = $(35.1 \pm 1.6) \%$

PD increases with energy (up to 80%!!), but the PA stays constant (*Zane et al. 2023*).
 The model foresees the coexistence of a warm condensed region and a hot atmospheric spot to explain (1) the low energy smaller polarization
 (2) the higher high polarization

Due to the small size of the emitting regions, QED Vacuum Birefringence cannot be probed yet (*Zane et al. 2023*).

Accreting NS – X-ray Pulsars Her X-1

An X-ray pulsar is a binary system made of a magnetized neutron star (10^{12} G) accreting matter from a normal stellar companion. Gas is accreted from the stellar companion and is channeled by the neutron star's magnetic field on to the magnetic poles producing two or more localized X-ray hot spots.

Average PD = $(8.6 \pm 0.5)\%$

X-ray pulsars are predicted (Meszaros et al., 1988, Caiazzo and Heyl, 2021, to be very highly polarized, because of the two different opacities while the polarization is lower than expected, but detected with very high significance in a number of sources, e.g. Her X-1

([Doroshenko et al. 2022](#)), Cen X-3 ([Tsyganov et al. 2022](#)), Vela X-1

([Poutanen et al. 2023](#)), GRO J1008-57 ([Tsyganov et al. 2023](#)) + ...

21/06/2023

Advances in Space AstroParticle Physics, 19-23 June 2023, Perugia (It)

Doroshenko et al. 2022

Determination of geometrical parameters

Table 1 | Orbital and pulsar geometrical parameters of Her X-1

$\chi_{p,*}$	θ	i_p	$\chi_{orb,*}$	i_{orb}
deg	deg	deg	deg	deg

Accreting Stellar-mass BH

The role of the jet

The geometry of the corona

The BH spin

Polarimetry of Black Holes in soft state can probe General Relativistic effects with the measurement of the BH Spin because the inner disk touches the Innermost circular orbits and the polarization angle rotates with energy with a spin-dependent rotation amplitude.

Polarimetry of Black Holes in Hard State can probe the coronal geometry and the jet-Corona interplay.

Cyg X-1 Low-Hard state

Cyg X-1 observed for about 250 ks in hard state, in coordination with NICER and NuSTAR

Krawczynsky, H. et al., 2022

Cyg X-1 in hard state

Polarization degree (2-8 keV): 4.0 ± 0.2

Larger than expected given the $\approx 30^\circ$ orbital inclination

Misalignment between the inner accretion flow and the orbital plane?

Flattish configuration of the emitting region

Polarization angle parallel to the radio jet

Observational evidence of link between disc and jet

Sandwich Corona geometry favored. Lamp-post/Cone excluded.

Polarimetry from Extragalactic Sources

Synchrotron-dominated

Blazars, multi- λ polarimetry probes **the structure** of the jet and of its magnetic field

Inverse Compton dominated

Blazars, multi- λ polarimetry observations can determine:

- **the composition of the jet** (hadronic vs. leptonic, Zhang & Bottcher, 2013)
- **the origin of the seed photons**
 Synchrotron-Self Compton (SSC) or External Compton (EC) (Celotti & Matt, 1994; Poutanen 1994)

A blazar is an active galactic nucleus (AGN) with a relativistic jet directed closely towards the observer. Relativistic beaming from the jet makes blazars appear much brighter than they would be if the jet were pointed in a direction away from Earth.

High Synchrotron peaked

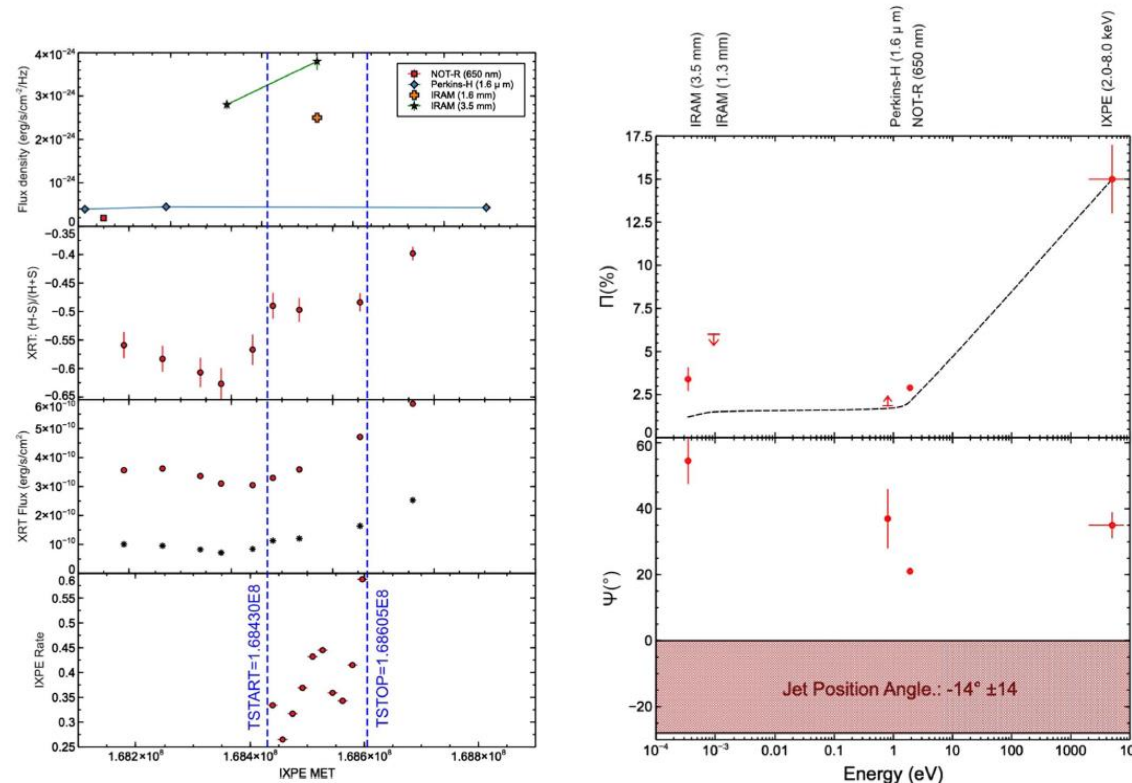

Blazars are promising sources for X-ray polarimetry. High Synchrotron Peak Blazars like Mrk 501 (*Liodakis et al. 2022*) and Mrk 421 (*Di Gesu et al. 2022*) are indeed significantly polarized. Multifrequency observations permit to discriminate among models.

IC peak sources are instead much less polarized (e.g. Cen A, *Ehlert et al. 2022*, BL Lac, *Middei et al. 2022*).

Multi-wavelength campaign from radio to X-ray was performed for Mrk 421

Mrk 421 was observed three times each time with 100 ks net observing time
 This work refers to the first observation occurred in May 4th – May 6th 2022

100 ks observing time

The polarization degree in X-rays is 7 times larger than in the optical and millimetric.

- The polarization is stable in degree (below +/- 4 %) and angle (below +/- 7°)

The particle emitting mm/IR/optical/X-rays are energy stratified as in Mrk 501.

The polarization vector is expected to be parallel to the radio jet but is not. A misalignment is possible between radio jet and jet regions where the X-rays are produced.

... but multiple observations of these sources show a significant variability in the polarization e.g. a rotation of 360° in 4.5 days (di Gesu et al., 2023, Nature Astronomy)

Di Gesu et al., 2022

RADIO QUIET AGN (POLARIMETRY DETERMINES THE GEOMETRY OF THE CORONA)

Hot
Corona

About 6 days of net observation

- The primary X-ray emission in AGN is due to Comptonization of soft optical/UV photons from the disk.
- The Comptonization happens in a hot corona located possibly above the disk.
- While Spectroscopy is capable to determine the physical status of the corona, it is rather insensitive to its geometry

Magnetic instabilities in the disk ?

Magnetic reconnection

Base of jet ?

The geometry of the corona can be probed by means of X-ray polarimetry.

Three unobscured RQ AGN have been observed:

MCG-5-23-16 – PD <3.2% (Marinucci et al. 2022, Tagliacozzo et al. 2023). Possibly aligned with the NLR axis. Slab (or wedge) preferred for the corona

Similar results for **IC4329A** (Ingram et al. 2023)

Positive detection in **NGC 4151** (Gianolli et al. 2023). PD=4.9±1.1%, aligned with the radio jet. Again, slab or wedge corona preferred

Compton-thick AGN

X-ray emission is dominated by reflection, so it should be highly polarized.

Polarization degree from the torus depends on the geometry of the system (inclination angle, torus opening angle)

The polarization vector is expected to be orthogonal to the torus axis.

The ionization cone/NLR may also scatter (and polarize) the primary emission.

Polarization vectors from ionization cone and torus are the same, if coaligned.

CIRCINUS GALAXY (URSINI ET AL., 2022)

- 70 % of local AGNs are obscured by gas and dust
- The obscuring medium is geometrically thick and axisymmetric (torus)
- If the column density $N_H > 1/\sigma_T = 1.5 \times 10^{24} \text{ cm}^{-2}$ they are called Compton thick
- The X-ray spectrum is dominated by reflection from both neutral (cold) and ionized (warm) matter surrounding the nucleus.

Circinus galaxy is a close AGN ($D = 4.2 \text{ Mpc}$).

It shows prominent $[\text{O III}]$ ionization cone, starburst rings and a radio jet
On sybparsec scales shows an edge on, accretion disk (from H_2O maser emission at 1.3 cm). $F_{2-10 \text{ keV}} = 1.5 \times 10^{-11} \text{ cgs}$

Simultaneous Chandra observation were used to monitor and model the spectrum of two ULXs within the extraction region of IXPE.

In 2-4 keV and 4-6 keV polarization is detected by more than 99 % CL. In 4-6

in reflection dominated AGNs the polarization of the reflected component is perpendicular to the torus axis.

Cold reflection

the cold reflector IXPE measured a 2-6 keV
polarization of:
 $P = 28 \% \pm 7\%$ and $\Theta = 18^\circ \pm 5^\circ$

68 %, 90 % 99 %

Jet, ionization cone and torus axis are aligned

The IXPE baseline program ends on February 2024.

The next NASA senior review for mission is foreseen in 2025.

NASA on 6 June 2023 approved an extension of IXPE until September 2025.

GO program is at the present time foreseen from February 24 to September 2025

Di Gesu, Nature Astronomy in press

Was the galactic center active 200 years ago ?

Galactic Center molecular clouds (MC) are known X-ray sources

- Are MCs reflecting X-rays from Sgr A* ? (supermassive black hole in the GC)
 - X-radiation would be *highly polarized* perpendicular to plane of reflection and indicates the direction back to Sgr A*
 - Sgr A* X-ray luminosity was 10^6 larger ≈ 300 years ago

Was the galactic center active 200 years ago ?

2.8 σ result. Polarization angle consistent with Sgr A* as the origin of the illuminating radiation.

From the polarization degree, two solutions for the age of the burst: ~30 or ~200 years ago. Second solution much more probable a flare 30 years old should have been visible.

Marin et al., Nature in press (June 2021)

Recap of Cyg X-1 high energy polarimetry

Chattopadhyay et al. 2023

In the LSP **BL Lac** X-ray emission is no longer dominated by electron Synchrotron. The source was pretty faint when observed by IXPE, and only an u.l. of 12.6% (99% c.l.) to the polarization degree could be obtained (*Middei et al. 2022*).

Hadronic models disfavoured in this source!

IXPE Obs. 1

IXPE Obs. 2

But polarization detected later on during an outburst (*Peirson et al 2023*) →

Two modes, with very different opacities

Ordinary mode: E field parallel to the k-B plane

Extraordinary mode: E field perpendicular
to the k-B plane

The X-mode from deeper, hotter layers

The radiation emerging from an atmosphere very likely is mostly extraordinary mode because the opacity is smaller

21/06/2023 IXPE is working great. Consider to participate to the IXPE GO program!

Weakly Magnetized Accreting NS

Comparison with theoretical predictions shows that the X-ray emitting region of GS 1826-238 either has a spherical symmetry or the system is less inclined than believed

For the other sources, and in particular for Cyg X-2 where the polarization is parallel to the radio jet, emission in the spreading layer (plus contribution from reflection) is the most likely explanation

Weakly Magnetized Accreting NS

Not pulsating accreting NS were expected to be much less polarized (e.g. *Gnarini et al. 2022*). IXPE is confirming this prediction, with a tight upper limit for GS 1826-238 (*Capitanio et al. 2023*) but a positive detection for Cyg X-2 (*Farinelli et al. 2023*), GX9+9 (*Ursini et al. 2023*), and XTEJ1701-462 (*Cocchi et al. 2023*)

X-ray spectroscopy can constrain the physical parameters of the corona.
 However, it is almost insensitive to its shape and location.
 Polarimetry, on the contrary, is very sensitive to the geometry of the corona, and can measure deviations from a spherical symmetry.
 The coronal geometry is related to its physical origin.

Three unobscured RQ AGN have been observed:

MCG-5-23-16 – PD < 3.2% (Marinucci et al. 2022, Tagliacozzo et al. 2023). Possibly aligned with the NLR axis. Slab (or wedge) preferred

Similar results for **IC4329A** (Ingram et al. 2023)
