

# A review of recent outgassing studies on mild and stainless steels

(mostly mild steel)

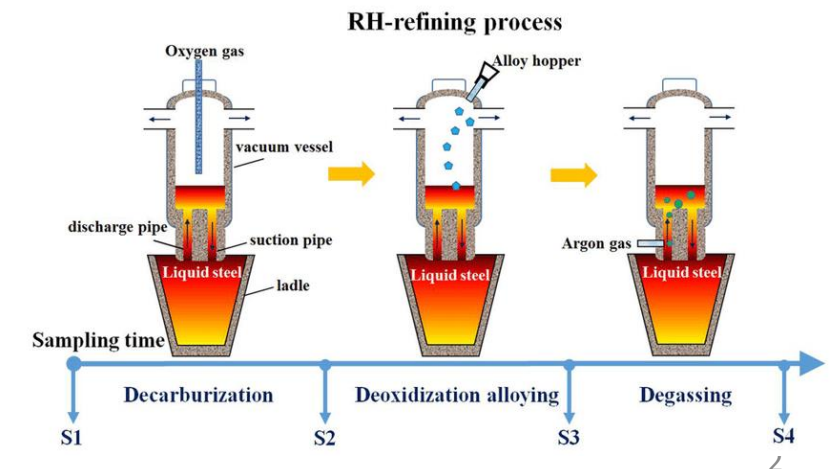

CERN, JLAB, NIST, WM

Presented by  
James Fedchak  
NIST

# Introduction: Why Mild Steel for Vacuum Systems?

- Commonly used as structural steel or for pipes
- Historically, not considered for UHV systems
- Modern secondary refining processes may reduce  $H_2$
- Possible low-cost alternative to stainless steel
  - Gravity Wave Detectors
  - Large vacuum systems
- Park et al (2016) obtained excellent outgassing results for 3 Korean mild steels
- CERN, JLAB, NIST & WM have confirmed Park et al's  $H_2$  results
- Pump-down (water outgassing) of mild-steel still a subject of research

# Outline

Recent mild-steel results from  
NIST, JLAB, CERN, W&M:

- Brief History of mild-steel outgassing
- Brief description of apparatus
  - National Institute for Standards and Technology (NIST)
  - Jefferson National Laboratory (JLAB)
  - William & Mary (WM)
  - CERN described in more detail by Ivo and Carlo
- Compare H<sub>2</sub> outgassing results (after 150 °C bake)
- Compare water outgassing results (pumpdown)

# Why Should Mild Steel have low outgassing?

To my knowledge, since 1950s, **mild steel** production **often** uses the **Ruhrstahl-Heraeus** process (RH) or other degassing process for **hydrogen reduction** and decarburization.

- RH is a secondary metallurgy process in which liquid steel is subjected to a vacuum treatment for decarburization and degassing  $H_2$  and  $O_2$

**Stainless steel** is typically produced from recycled steel in an electric arc furnace

- As produced, **most stainless steels contain significant dissolved  $H_2$**
- High temperature **heat-treatment** (vacuum-firing) is required to

We sent out 4 samples for hydrogen concentration testing

Titanium	40	1.0	3.68	1	9

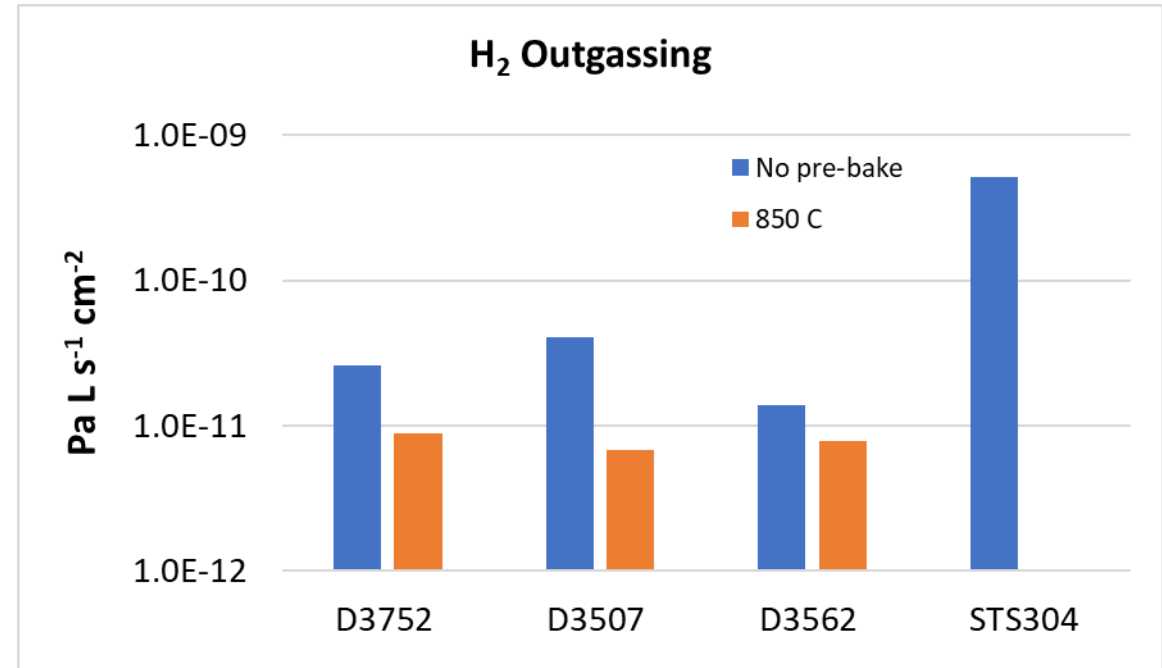

- Eley (1975) and Ishimori et al (1971), for e.g., show mild steel outgassing higher than stainless steel
- Back in the 1990's, Dylla and Blanchard questioned the values of outgassing for mild steel relative to SS
- According to Park et al. (2016), vacuum degassing was developed in the 1950's, but only 10% of Japanese plants used the process by the 1970's

Eley, R. J. (1975). Outgassing of vacuum materials-II. *Vacuum*, 25(8), 347–361.  
[https://doi.org/10.1016/0042-207X\(75\)91653-X](https://doi.org/10.1016/0042-207X(75)91653-X)

# Park et al 2016 H<sub>2</sub> Outgassing

3 Korean Mild Steels Tested: D3752, D307, D3562

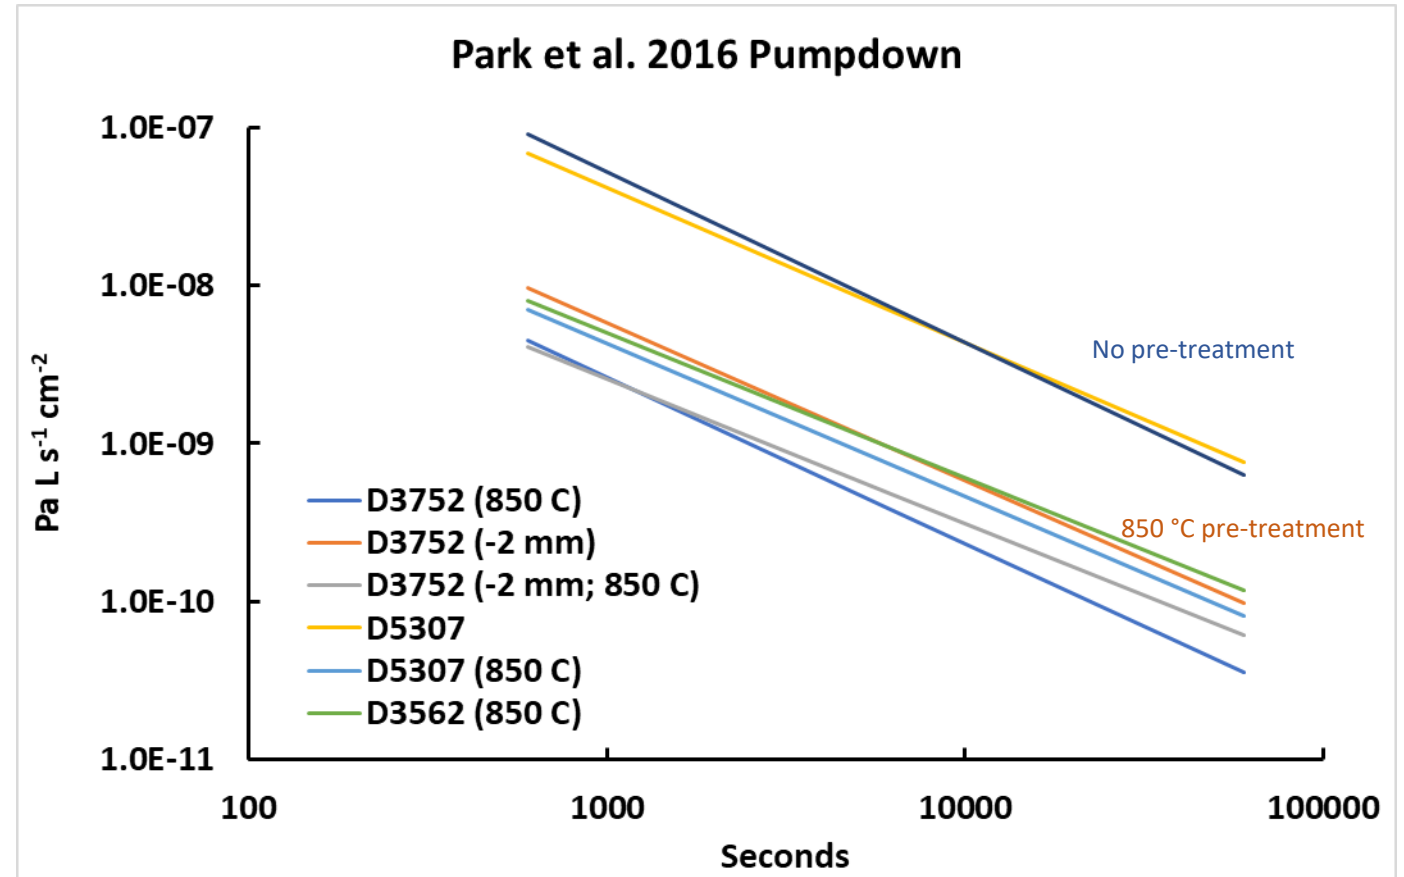

- Rate-of Rise (RoR) with spinning rotor gauge (SRG)
- 304 measurements similar to NIST and other benchmarks
- Mild steel better by more than 10X
- 850 °C shows modest improvement
  - (this will not be true for H<sub>2</sub>O outgassing)
- QUESTION: was there a background subtraction for non-mild-steel components?
  - Very important for low outgassing RoR measurements

sample chambers were baked at 150 °C for 48 h

# Park et al 2016 Pumpdown Curves

- Outgassing was measured at 24 °C after 48-h in situ bakeout followed by a 5-h N<sub>2</sub> exposure
- Not an air exposure?
- 2 to 3 orders of magnitude lower than stainless steel exposed to air
  - Same slope
- Baking at 850 °C lowered H<sub>2</sub>O outgassing

# NIST Outgassing Apparatus

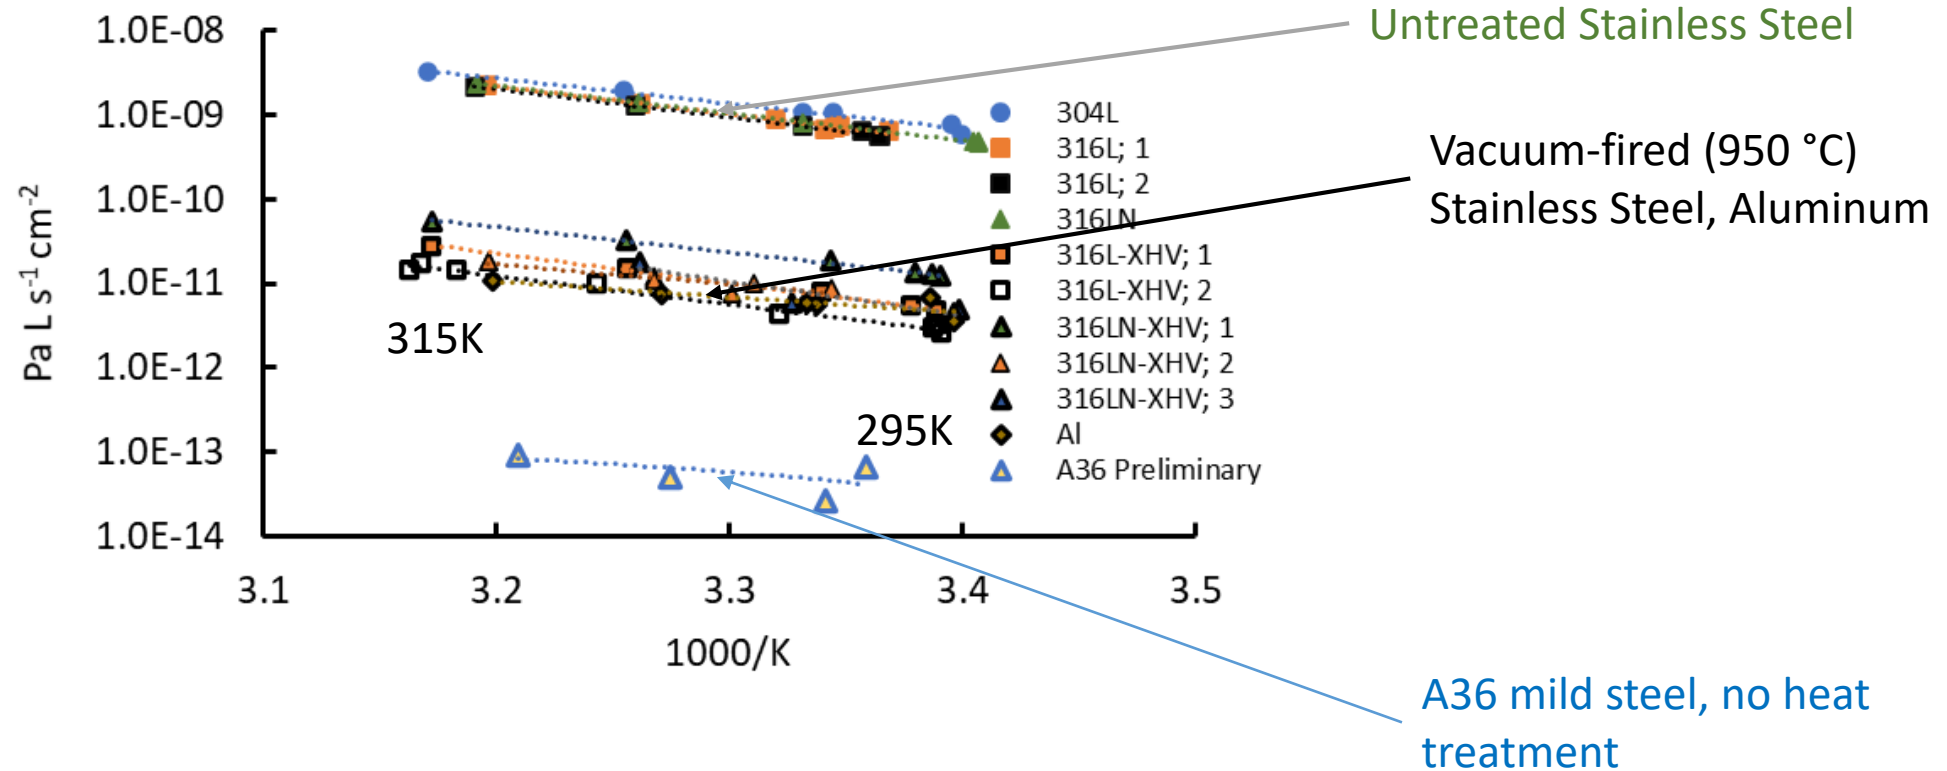

- Published outgassing results for 7 geometrically identical chamber– Applied Vacuum Division
  - $\approx 6.4$  L
  - $\approx 2000$  cm<sup>2</sup>
- H<sub>2</sub> Outgassing: rate of rise (RoR)
- Pumpdown: throughput method
- We add A36 mild steel

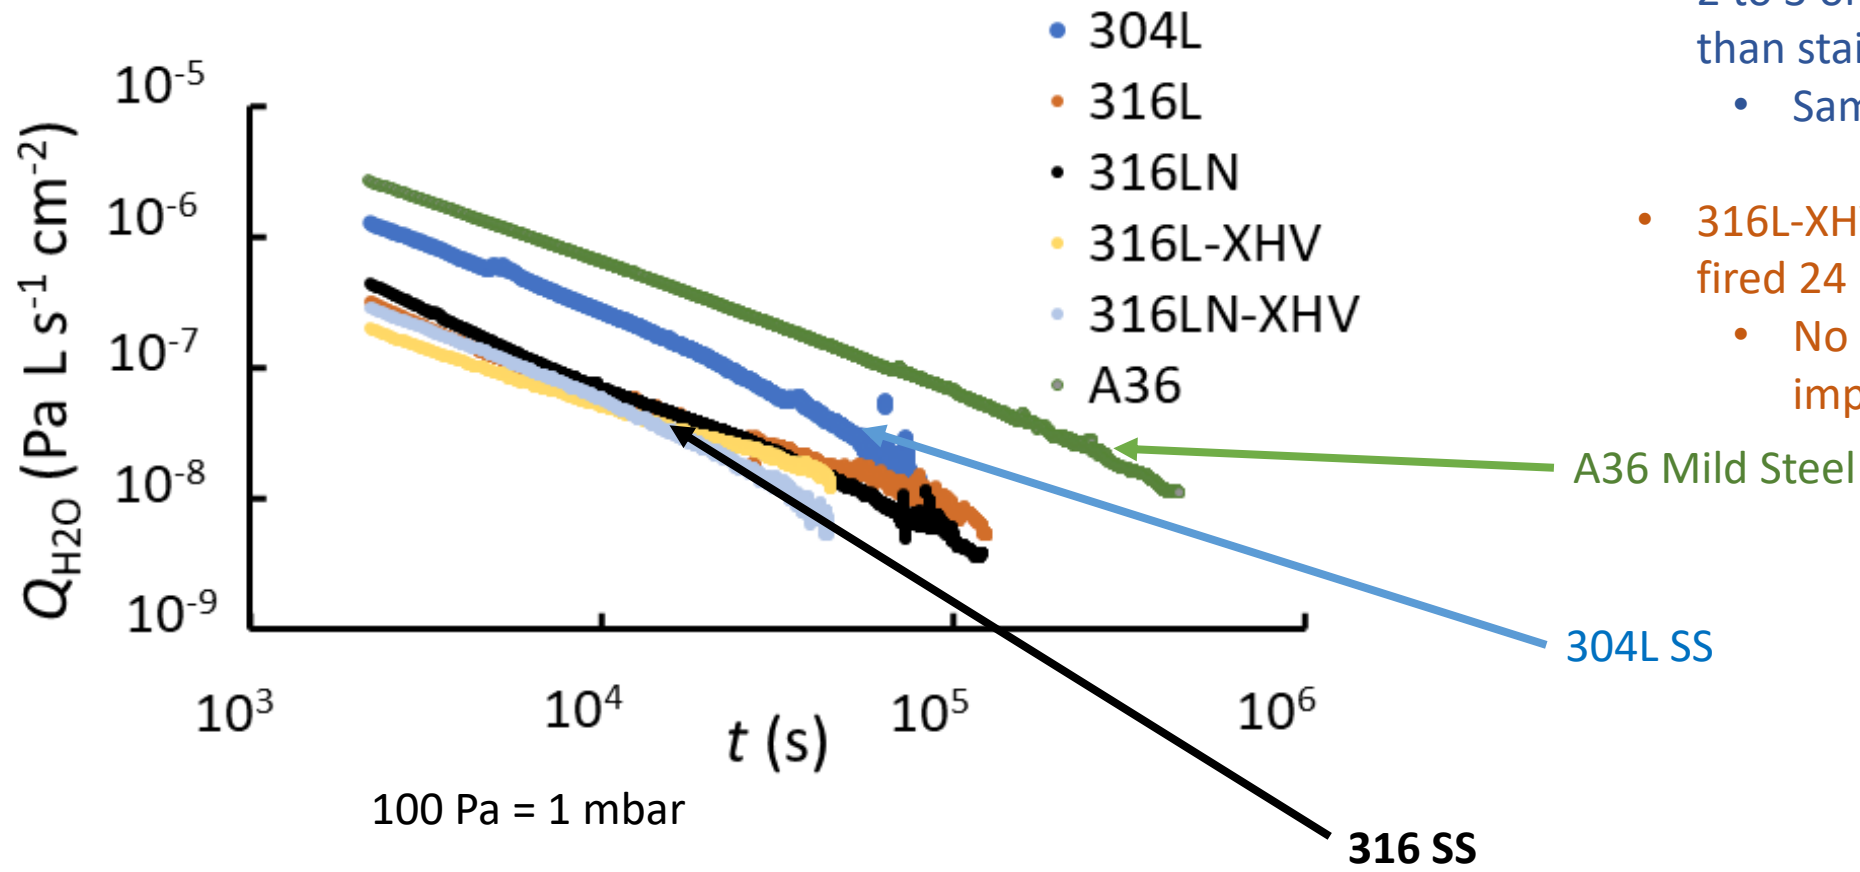

# NIST H<sub>2</sub> Outgassing data (A36 PRELIMINARY DATA)

100 Pa = 1 mbar

Chambers baked 125-150 °C for ≥ 3 days

# NIST Water Outgassing data (A36 PRELIMINARY DATA)

- Exposed to Air
- 2 to 3 orders of magnitude lower than stainless steel exposed to air
  - Same slope
- 316L-XHV and 316LN-XHV vacuum fired 24 h at 950 C.
  - No water outgassing improvement

# Pump Down setup

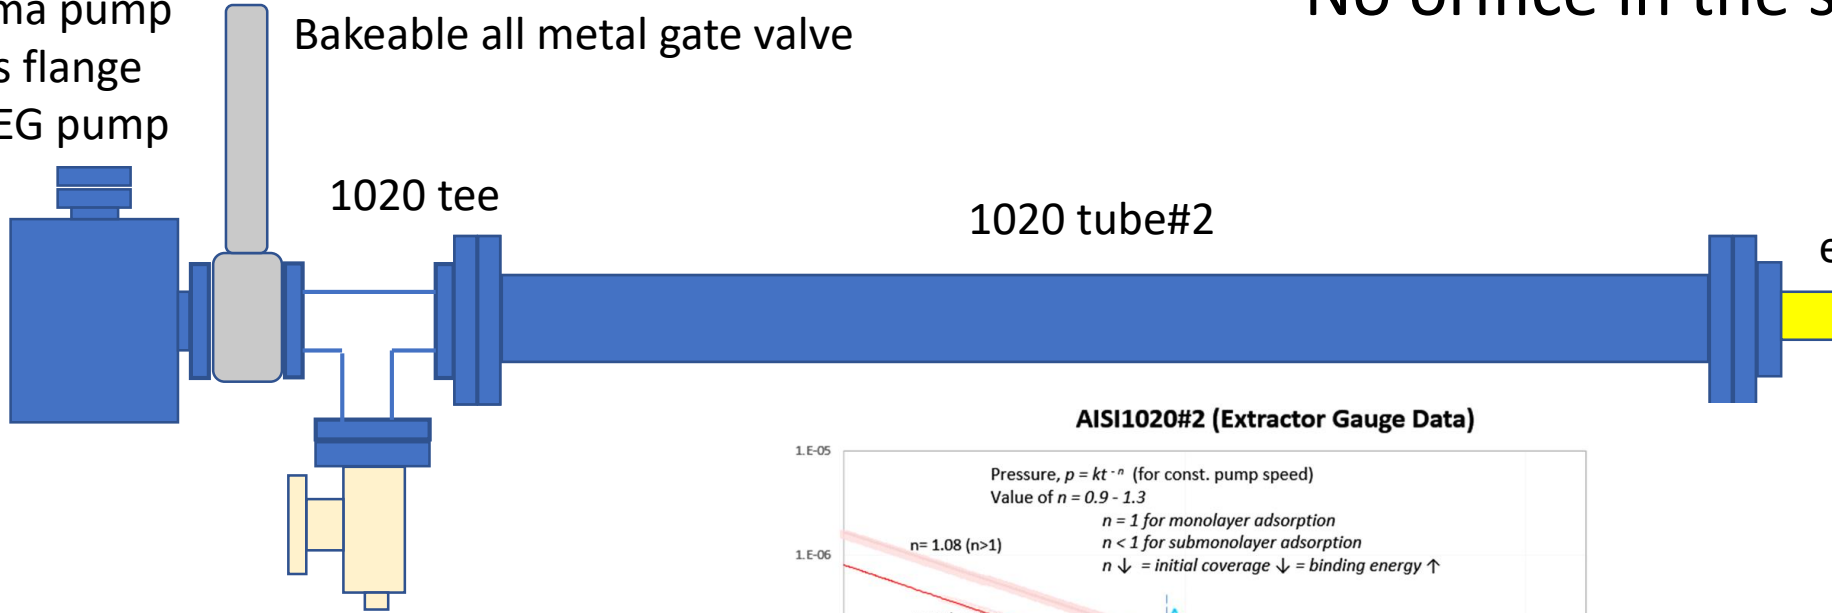

20 L/s Gamma pump  
with 50 L/s flange  
mounted NEG pump

Bakeable all metal gate valve

1020 tee

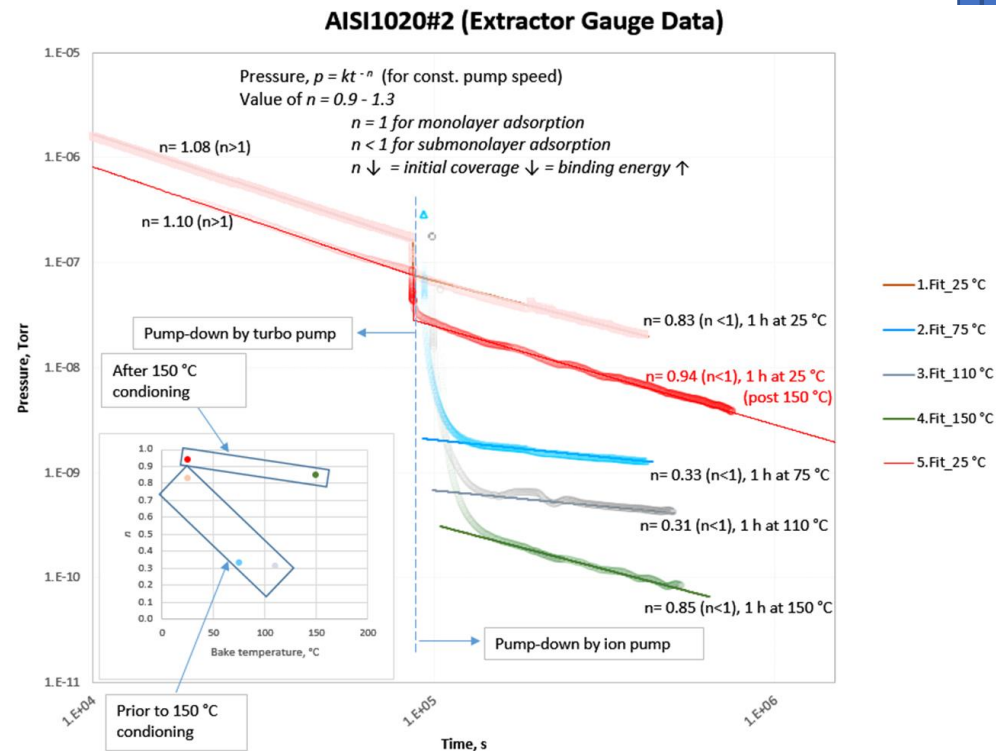

1020 tube#2

extractor

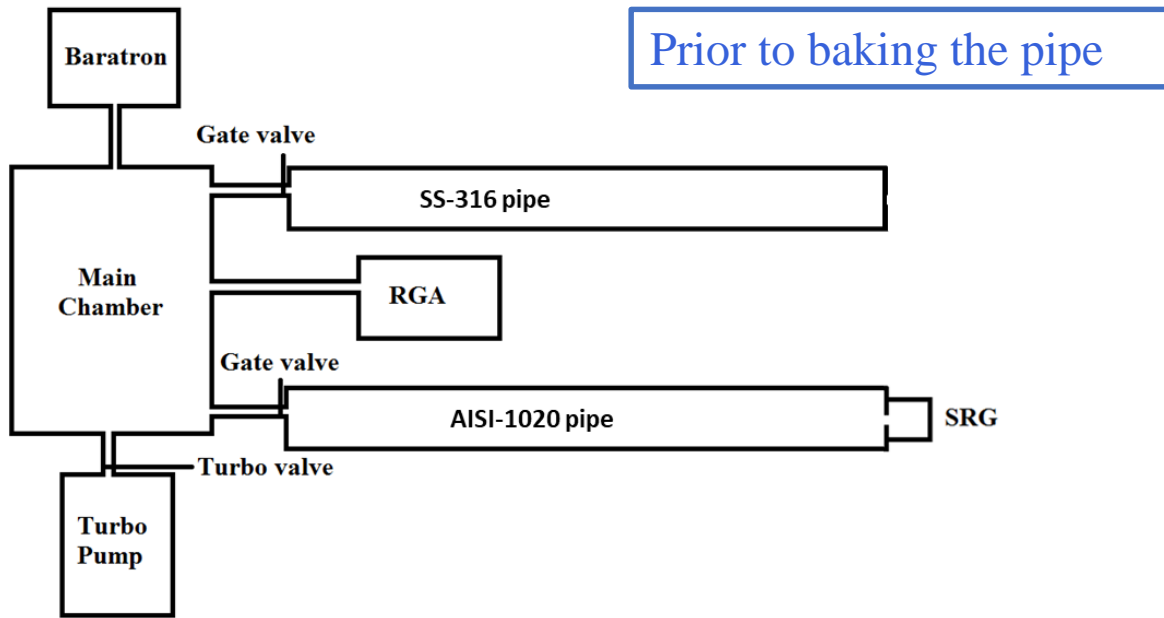

RA valve to turbo  
for pump down

No orifice in the system

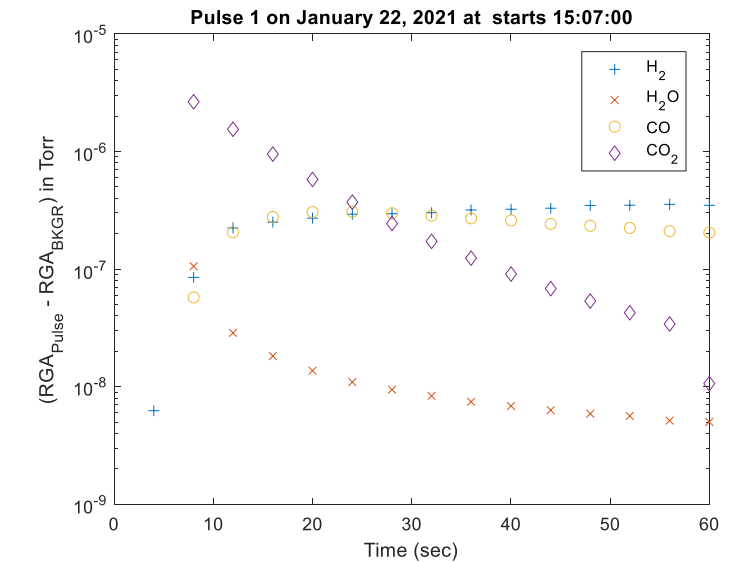

H<sub>2</sub> dominates by two orders of magnitude at 24C

The CO<sub>2</sub>:H<sub>2</sub> ratio increases at temperatures above 60C

CO<sub>2</sub> is 10 times larger than H<sub>2</sub> at 70C.

To determine the gas composition, we use a pulse gas release method:

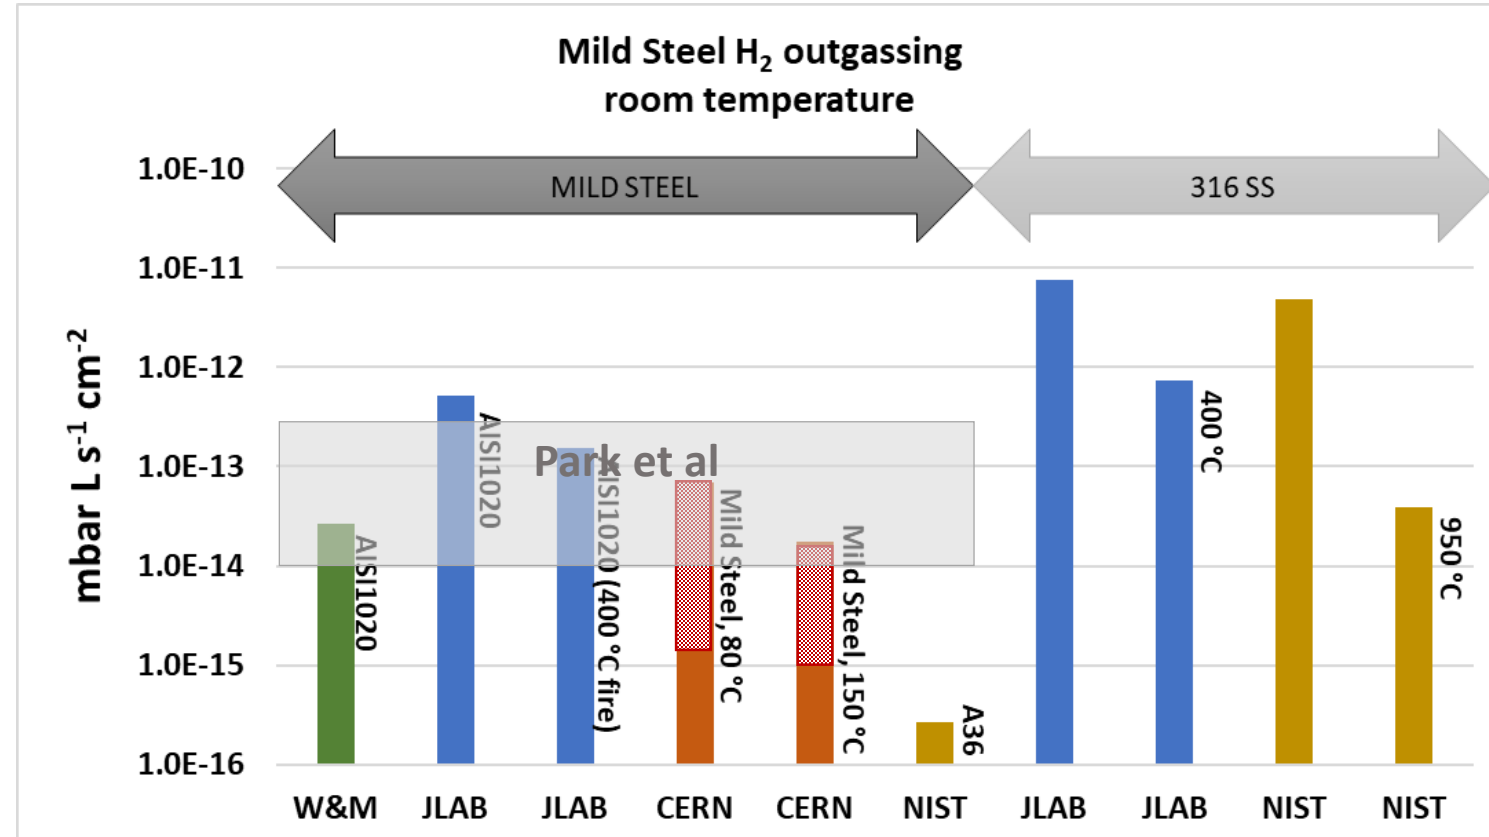

1. Begin by closing Turbo (4-5 seconds) to monitor outgassing of main chamber
2. Pulse pipe (for 1-3 seconds) to equilibrate pressures. The pipe and the RGA chamber have nearly equal volumes.
3. Observe the **time dependent** signals at selected *amu*. With *amu* = [2 14 15 16 18 28 44] scan time is reduced to 2 or 4 seconds.

# Mild Steel H<sub>2</sub> outgassing

Lab	Mild Steel	mbar L s <sup>-1</sup> cm <sup>-1</sup>
W&M	AISI1020, 150 °C, 48 h bake	2.6E-14
JLAB	AISI1020, 150 °C, 69 h bake	5.2E-13
JLAB	AISI1020 (pre-bake 400 °C), 150 °C, 48 h bake	1.5E-13
CERN	Mild Steel, 80 °C, 48 h	1.5E-15
CERN	Mild Steel, 80 °C, 48 h	7.0E-14
CERN	Mild Steel, 150 °C, 48 h	1.0E-15
CERN	Mild Steel, 150 °C, 48 h	1.7E-14
NIST	A36, 299 K, 100-150 C bake, 5 days	2.6E-16

Lab	Stainless Steel	mbar L s <sup>-1</sup> cm <sup>-1</sup>
JLAB	SS316, 150 °C, 48 h bake	7.6E-12
JLAB	SS316 (pre-bake 400 °C) 150 °C, 49 h	7.3E-13
NIST	316L	4.9E-12
NIST	316L-XHV (950 °C Fire)	3.9E-14

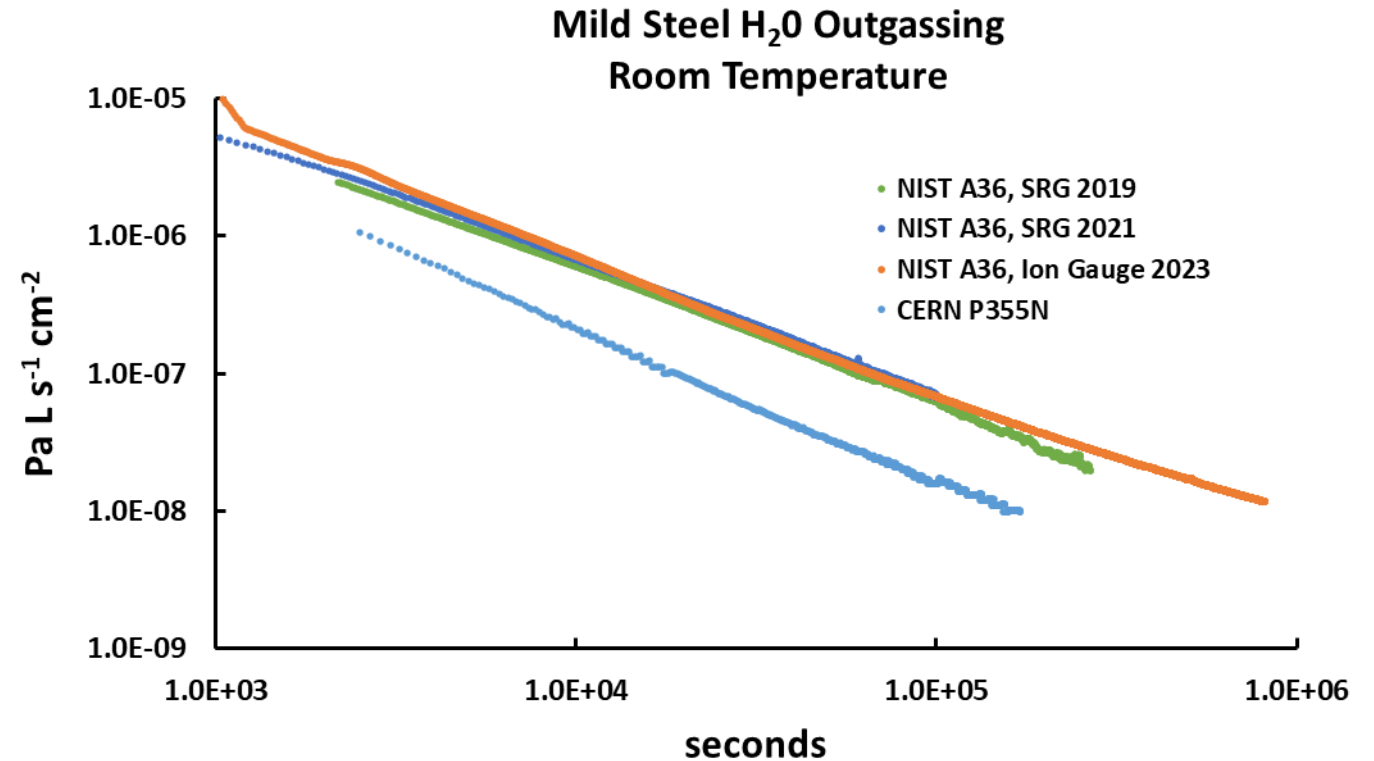

- 150 °C, minimum 48 hour bakes (except where noted)
- All exposed to air before bake
- Other constituents (H<sub>2</sub>O, CO CO<sub>2</sub>) likely present

**Evidence suggests that for a wide variety of mild steels H<sub>2</sub> outgassing will not be a concern for most applications**

# Mild Steel H<sub>2</sub>O Outgassing Comparison

Throughput Method: NIST & CERN

- NIST has measured A36 3 times over 4 years
  - Two different gauges: SRG & IG
  - Very consistent measurements
- CERN measured 355N mild steel
  - 355N may be close to order of magnitude lower than A36
  - Similar slope

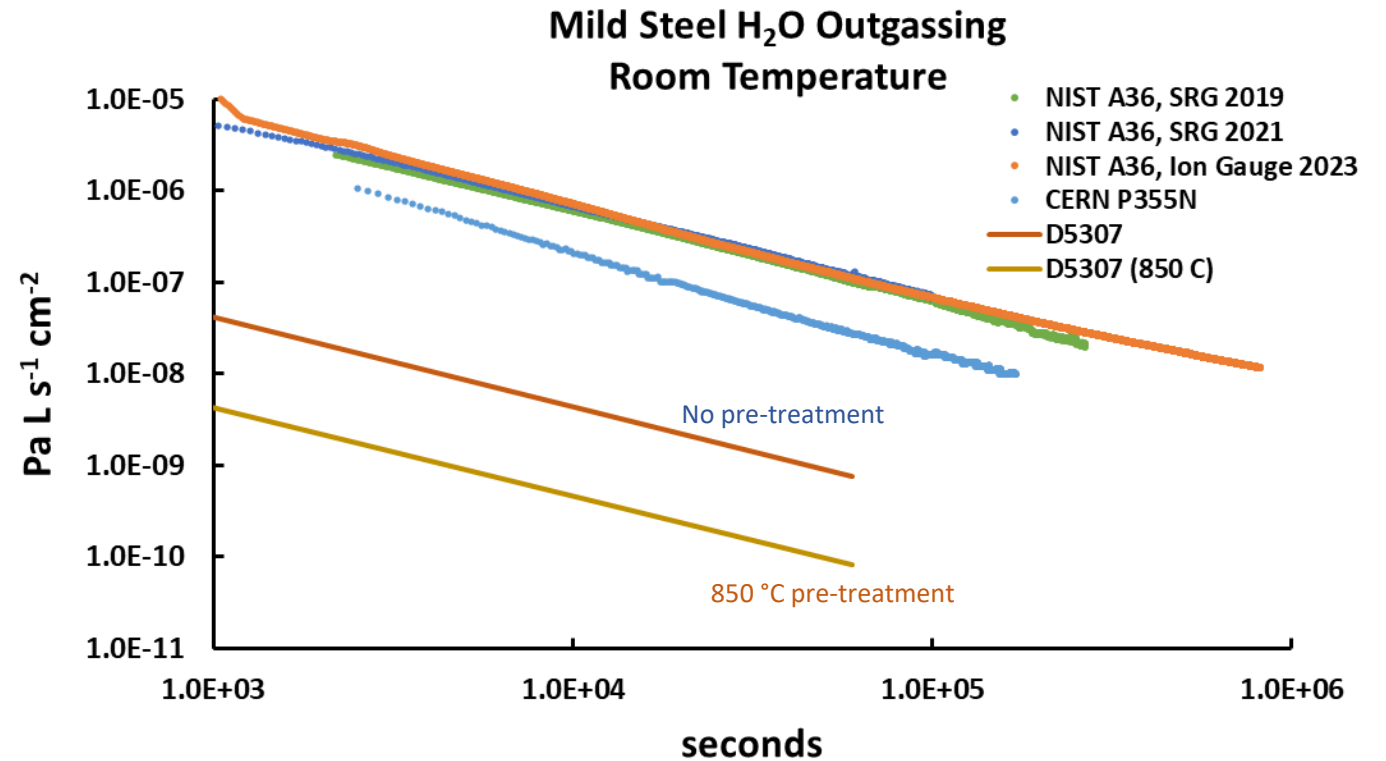

# Mild Steel H<sub>2</sub>O Outgassing Comparison

Throughput Method: NIST, CERN & Park

- Park et al 2016 results for D3507 (Korean) are 1 to 3 orders of magnitude lower
  - They probably vented with N<sub>2</sub> not air
- Similar slope to CERN and NIST

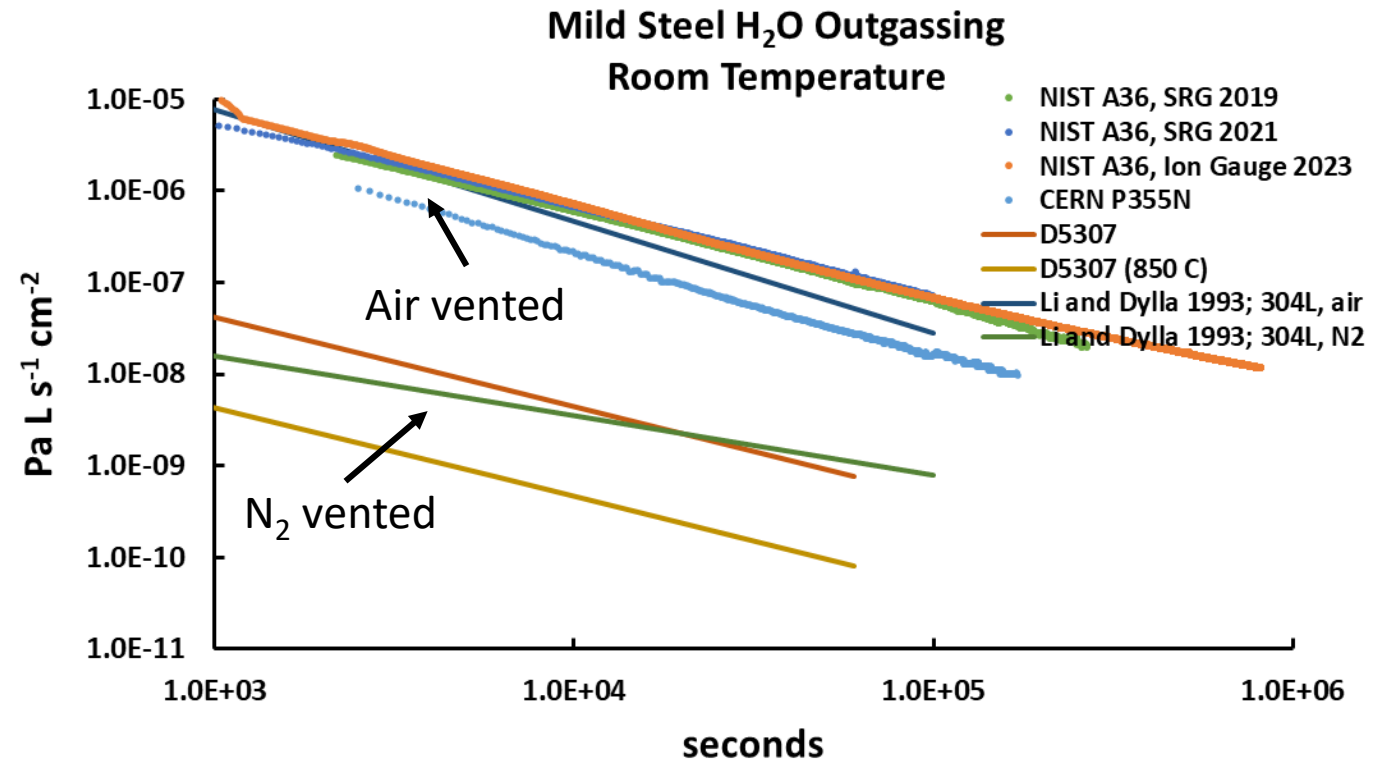

# Mild Steel H<sub>2</sub>O Outgassing Comparison

Throughput Method: NIST, CERN, Park, & Dylla

- Li & Dylla 1993 vented with air and dry N<sub>2</sub>
- CERN & NIST Data same order of magnitude as air vented 304L SS
- Slope of mild steel may be slightly slower for mild steel
- Park et al 2016 results similar order of magnitude to N<sub>2</sub> vented 304L SS

Pumpdown of mild steel from air may not be any improvement over 304L SS. It may be a little worse.

# Wrapping up ...

- Untreated Mild Steel  $H_2$  outgassing is superior to stainless steel
  - Likely as good as, if not better than, Ti, vacuum-fired SS, or Al
- Water outgassing of untreated mild steel is similar to, or maybe worse, than stainless steel
- There is an indication that heat treatment improves mild steel water outgassing performance
  - Stainless steel water outgassing is not improved by this

## Going forward:

- Modifying mild steel surface may improve water outgassing
  - We want to develop a process for magnetite coating
  - Test Magnetite coated mild steel for water outgassing
- Still need full investigation of water outgassing as a function of temperature

*Aspect of the internal surface after accumulation measurements*

*Aspect of the internal surface after pressure measurements*

**NIST**

**Thank You!**

Many thanks to Emmanuel  
Newsome, Fred Dylla and the  
folks at JLAB, WM, & CERN!
