28 Mar 2023

# Gas sources for ET-LF

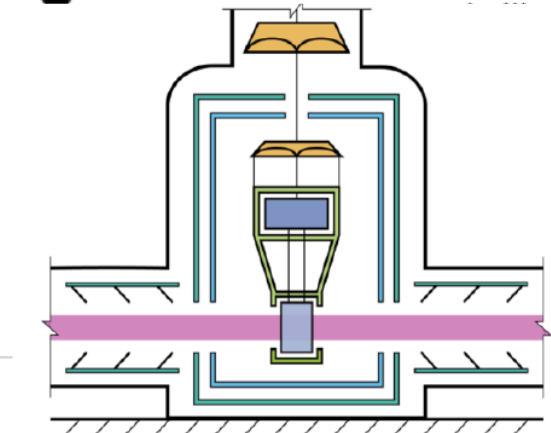

- Consideration of all gas sources and simplified geometry with TPMC model (in-house code ProVac3D)
- Disadvantageous L/D ratio → HPC (10,000 cores) required
- Find influences and sensitivities  
→ Knowledge where effort is mostly needed
  
- First source – from 10 km long beam pipe
- Second source – from upper part of suspension tower
- Third source – from adjacent tower with much higher flow
  
- All combined flows have to fulfill pressure and adsorption requirements

# Sensitivity study to find the 'best' solution

Translates the physics requirements into engineering requirements  
 → Temperatures, fluxes and to be pumped amounts

Output of this workflow: Allocation of capture coefficients to each surface such that all design targets are achieved with measures that have been shown to have the highest impact.

# Beam pipe gas source towards cryogenic mirror

# Differentiation between hydrogen and water (I)

■ Step 1: **Hydrogen pressure profile** (neglecting water flow rate towards cryogenic mirror)

■ Assumptions:

- Total outgassing is 50/50 H<sub>2</sub>/H<sub>2</sub>O
- Outgassing of  $2.5 \cdot 10^{-11}$  Pa m<sup>3</sup>/(s m<sup>2</sup>) each
- Warm pumping station with 5 m<sup>3</sup>/s every 500 m
- Cryopump with **30 m** length, sticking coefficient for H<sub>2</sub> varied (0.25...1)

→ Reduction of pumping speed flattens the curve (but needs low outgassing!)

→ Cryopump for hydrogen may not be needed

Finding: There is no need for a strong hydrogen pumping cryopump at the beampipe side of the cryostat.

# Cryopump for H<sub>2</sub> needed?

- 30 m cryopump at 10 km beam pipe only 80 K [for water & Co] but with no H<sub>2</sub> pumping capacity.
- Hydrogen pumped only by last warm pump station (added at warm end of cryopump)
- Resulting H<sub>2</sub> pressure at mirror  $\sim 3 \cdot 10^{-11}$  mbar

Finding: Indeed, there is no need for a strong hydrogen pumping cryopump at the beampipe side of the cryostat.

# Differentiation between hydrogen and water (II)

- Step 2: **Water flow rate towards cryogenic mirror** (neglecting hydrogen pressure profile)

- Assumptions:

- Total outgassing is 50/50 H<sub>2</sub>/H<sub>2</sub>O
- Outgassing of 2.5·10<sup>-11</sup> Pa m<sup>3</sup>/(s m<sup>2</sup>) each
- Warm pump stations with 5 m<sup>3</sup>/s every 500 m
- Cryopump with different lengths, sticking coefficient for H<sub>2</sub>O (c=1)

Finding: The cryopump at the beampipe side of the cryostat can be operated at 80 K (only water pump, but this very effectively.)

- Low flow towards the cryogenic mirror can be achieved with cryopump

→ Shorter cryopump might be sufficient to have acceptable time until water monolayer build-up

| #  | Outgassing rate (Pa m <sup>3</sup> /(s m <sup>2</sup> )) | Length of cryopump (m) | Flow towards mirror (Pa m <sup>3</sup> /s) |
|----|--|------------------------|--|
| 23 | 2.50E-11   | 5                      | <b>2.5E-10</b>                             |
| 22 | 2.50E-11   | 10                     | <b>1.2E-10</b>                             |
| 21 | 2.50E-11   | 20                     | <b>5.5E-11</b>                             |
| 17 | 2.50E-11   | 30                     | <b>3.1E-11</b>                             |
| 18 | 2.50E-11   | 50                     | <b>1.6E-11</b>                             |
| 19 | 2.50E-11   | 70                     | <b>1.1E-11</b>                             |

# Results

- Stronger pumping to compensate higher outgassing in beam pipe is not helpful.
  - Required beam pipe conditions have to be established by low outgassing rates, not by stronger pumping.
- Beam pipe vacuum strongly decoupled from cryostat vacuum.
- Hydrogen pumping not needed in the cryopump at the beampipe side of the cryostat.
- Water is well manageable by a 80 K cryopump.

# Upper tower gas source

# Conductance minimisation – cone solution

## Assumptions

- Suspension diameter: 12 mm
- Clearance at bottom: 6 mm
- Tube length: 300 mm, 500 mm, 800 mm or 1000 mm
- Clearance at top: 1 mm or 0.5 mm

with x/y table moving the smaller opening with the position of the suspension cable

# Calculated gas flows from tower to mirror

|         | Radius suspension | Radius opening | Radius opening 2 | Clearance  | Orifice/tube length | Transmission surface | Transmission probability | Conductance         | Gas flow to mirror     |
|---------|-------------------|----------------|------------------|------------|---------------------|----------------------|--------------------------|---------------------|------------------------|

# Results

- Some geometric solution of tower isolation is needed (tube)
- Extra pressure reduction by factor  $\sim 10$  in tower is advisable (by additional means to reduce outgassing and/or increase pumping speed, most probably cryopumping).
- High uncertainties in outgassing composition and tower pressure
- Implementation of baffles possible
- Assumed value for further simulations:  **$2 \cdot 10^{-9} \text{ Pa} \cdot \text{m}^3/\text{s}$**

Finding: Pumping in upper tower and conductance minimisation assumed

# Adjacent tower gas source

# Details of third gas source

- Source from adjacent warm tower/optics
- Separated by only 50 m from cryogenic mirror
- Releasing high gas flow with  $10^{-7}$  Pa m<sup>3</sup>/s for H<sub>2</sub> and  $10^{-6}$  Pa m<sup>3</sup>/s for water
- Much higher flows as from other two sources
- Cryopump section needed to handle H<sub>2</sub> flow
- Low temperature cryopump section seems indispensable (3.7 K or 10 K with some dust-free sorbent (R&D))
- Water trapping with longer 80 K section

# Complete model established

- Three sources implemented
- With time evolving detailness (cold H<sub>2</sub> pumping marionette, cold inner cryostat shield pumping water – or even H<sub>2</sub>?, inhom. distribution on mirror?)

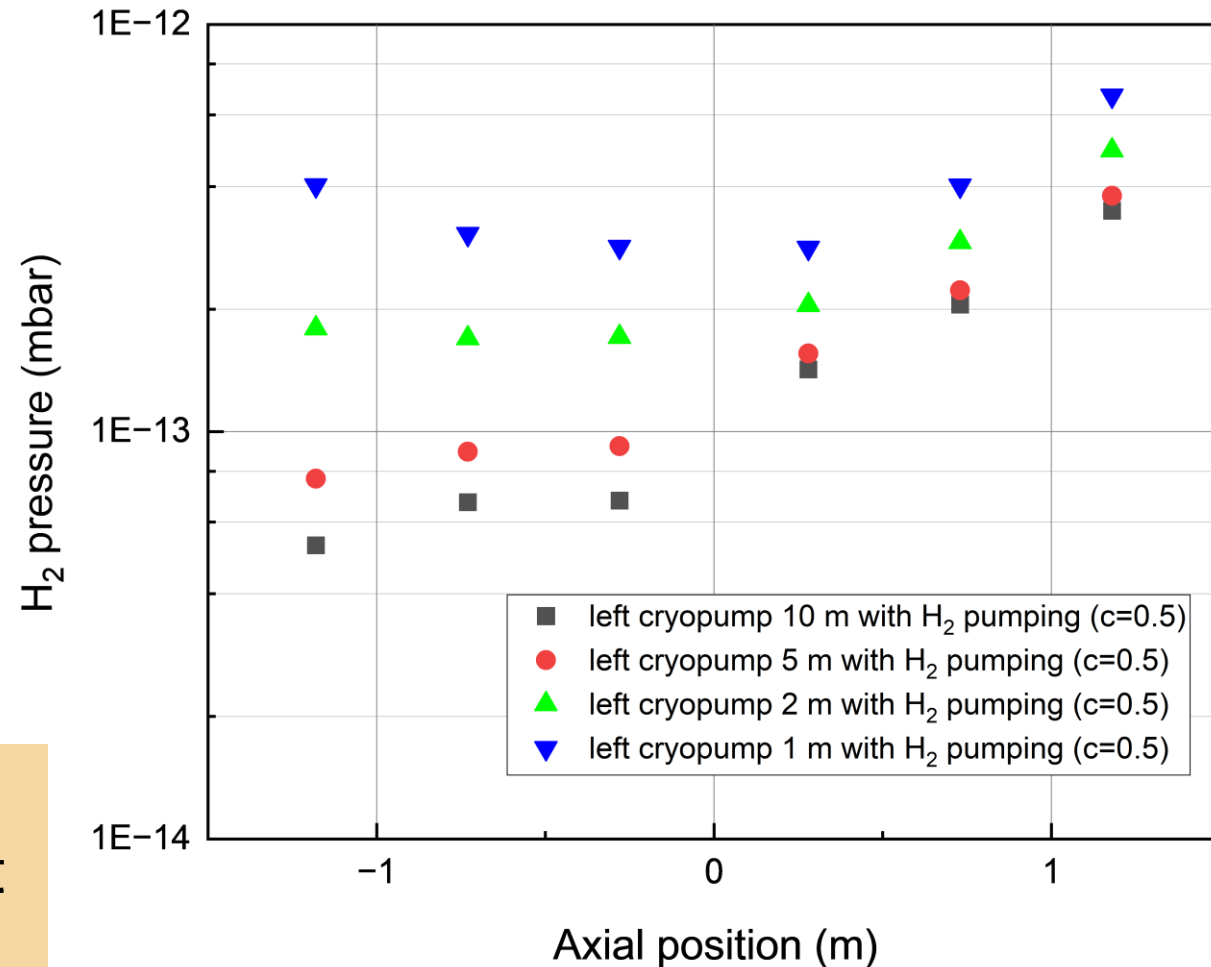

1 km more

# Hydrogen pressure near cryogenic mirror

- Consideration of all gas sources
- Short H<sub>2</sub> pumping at adjacent tower side is sufficient (still huge pumping speed)

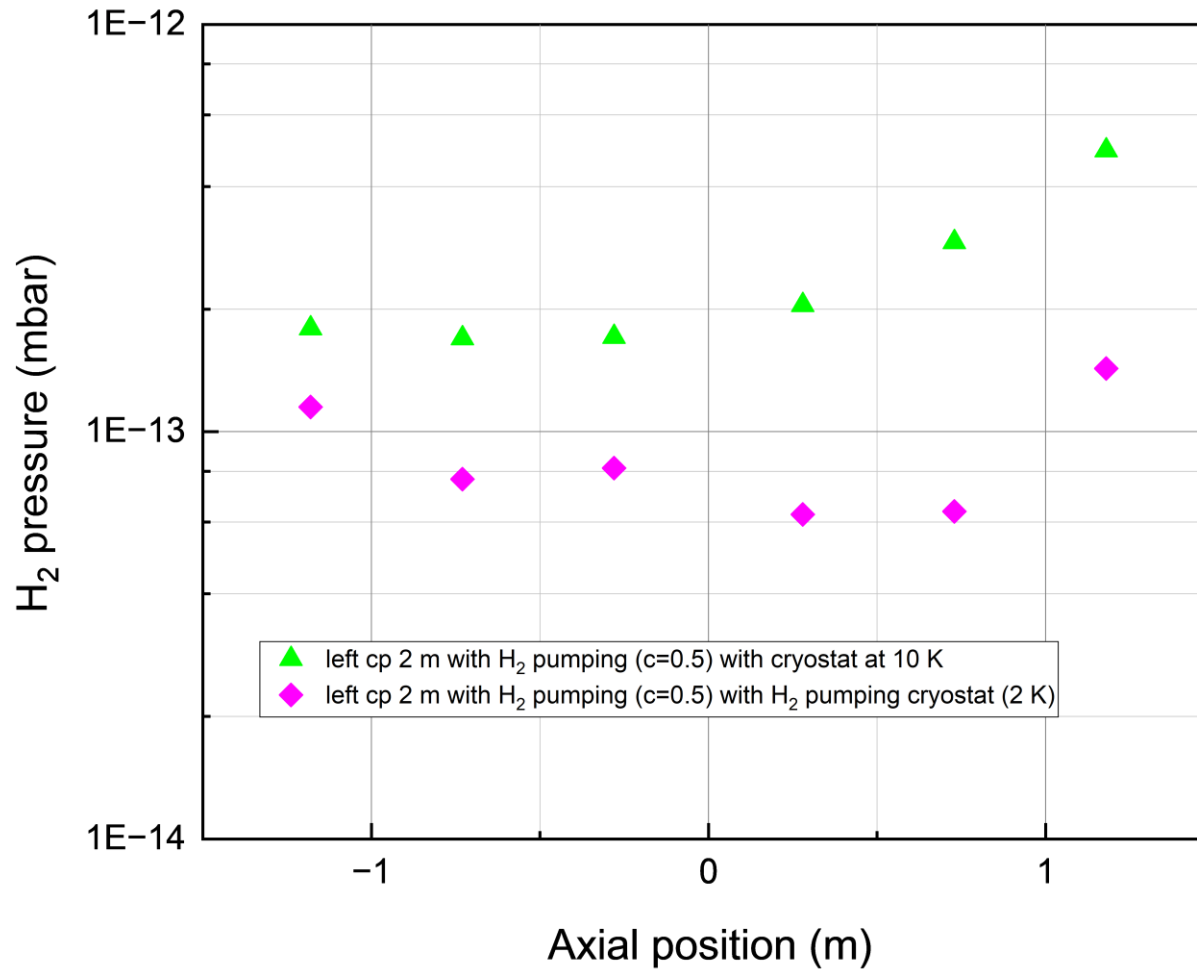

Finding: Short left cryopump section for H<sub>2</sub> needed, with 10 K and sorbent or 3.7 K without

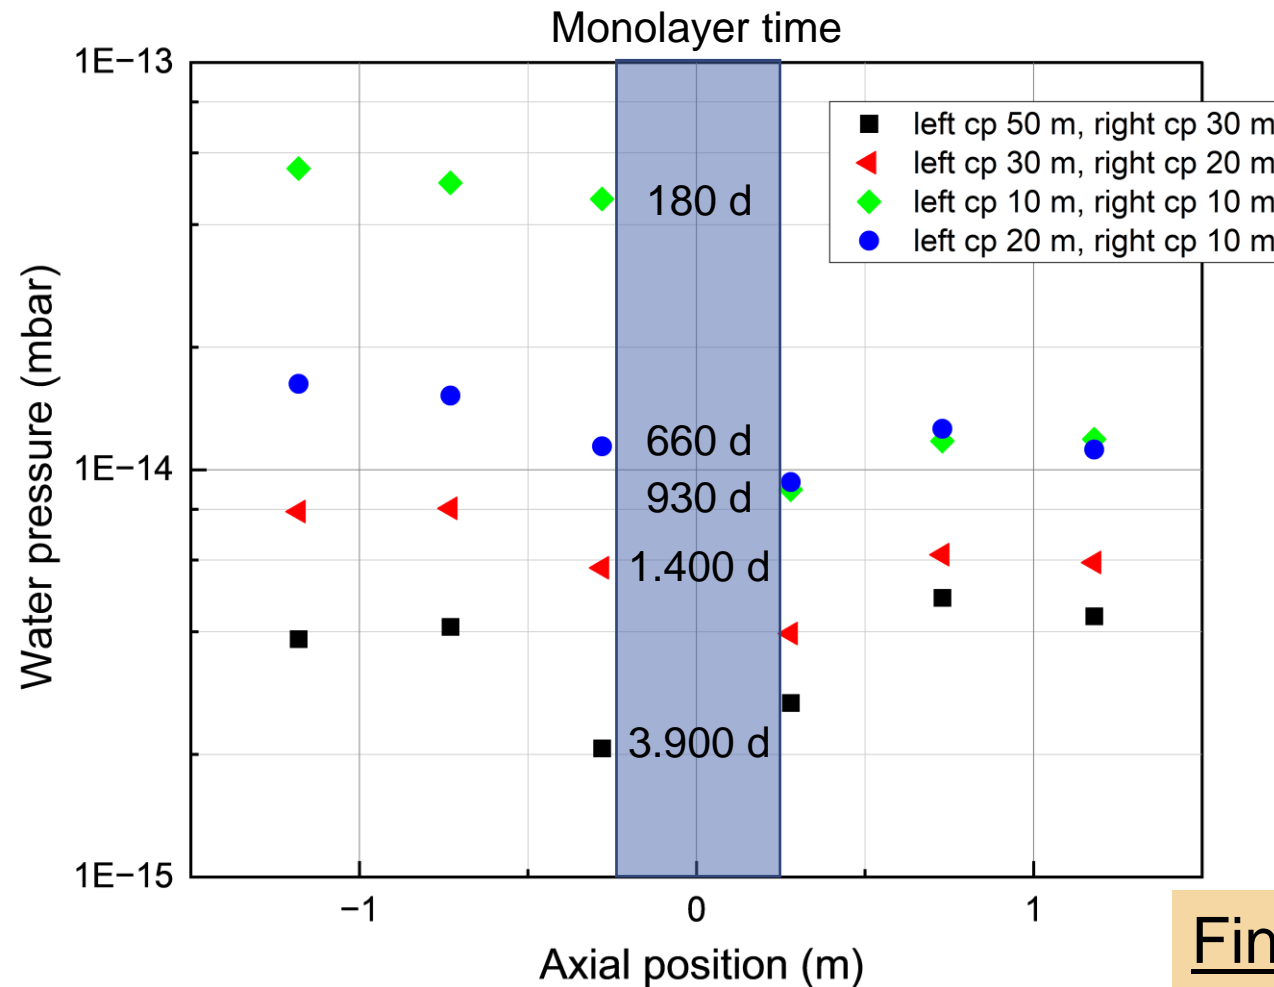

# Other pumping contributions

- Effect of additional hydrogen pumping by inner cryostat shield
- Water pumped by shield independent of temperature decision

# Water pressure at cryogenic mirror and frost formation

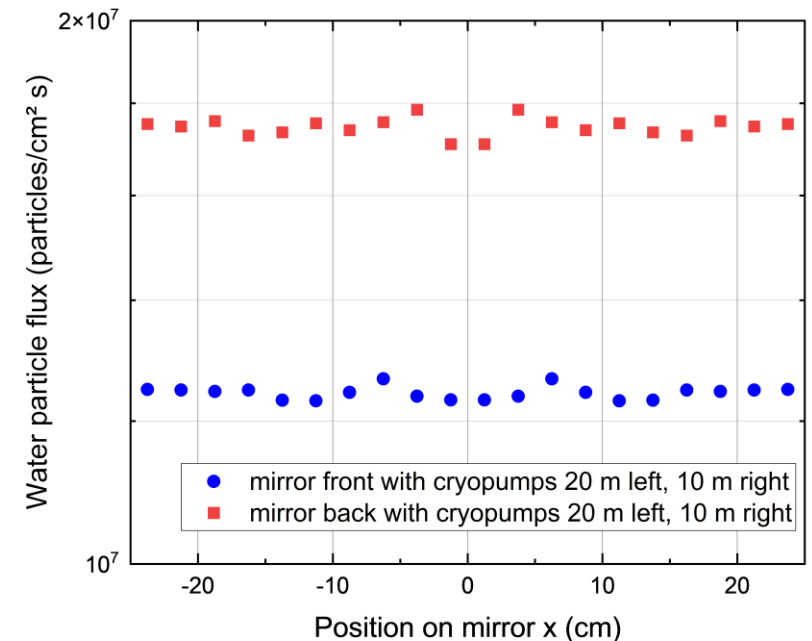

- Consideration of all sources
- Water pumping at 80 K  
→ 20 m and 10 m seem sufficient

Finding: Frost on mirror drives more than pressure. Long ML times feasible.

# Homogeneity of frost formation on mirror

- Inhomogeneity would result in lower acceptable time for ML formation (worst position drives the assessment)
- Implementation of segmented mirror in model and read out of particle impinging position
- Result: no significant inhomogeneity
- Plausible due to sticking of 1 for water at CP and so only direct flying water particles arrive on mirror from source 50 m away

**Finding: Homogenous frost formation.**

# Conclusions

- Source 1: cryopump 80 K for water trapping sufficient
- 10 km beam pipe conditions via low outgassing (instead of high pumping speed)
- Source 2: conductance minimisation plus (cryo)pumping in upper tower needed to reduce flow according needs
- More options will be studied (e.g. special water baffle upwards?)
- Source 3: cryopump section for hydrogen needed, additional to water pumping main section

→ Pressures around mirror:  $\text{H}_2$ :  $3 \cdot 10^{-13}$  mbar,  $\text{H}_2\text{O}$ :  $1 \cdot 10^{-14}$  mbar, water ice build-up ~2 years for 1 ML

# Next step: Cryopump design in tubes

- Cryopumps outside of free path in beampipe tubes of 1 (1.2) m diameter
- 0.25 m thickness needed (to be detailed and justified)
- 1.5 (1.7 m) + insulation diameter wherever a cryopump is contained
- 80 K shielding between cryopanel and backside (beam pipe wall)
- Hydroformed panels usually in fusion, here with reduced demands other options possible
- Shielding at ends of cryopump towards warm areas beside
- Modular system (panel and shield segments) → any length possible
- Cryogenic supply needs several in- and outlets for such long pumps
- Space and access demands for supply connections
- More detailed heat loads for cryoplant
- With developing concepts more precise heat loads on mirror
- With same code and modified model

Taylor-made cryopump panels for fusion experiment

# Heat load criticalities

# Heat load criticalities need input

- Pump concept sound for vacuum requirements
- But heat loads towards mirror (and 2 K cryostat shield) from 80 K are excessive
- Solutions have to be found based on input needed from noise and beam optics experts
- How close can actively cooled CP components be positioned towards mirror?
- Cryostat shields closing partially the opening of the beam pipe to reduce thermal radiation load from 80 K and 300 K. To which extent acceptable for beam optics? 0.62 m or mirror  $\varnothing$ ?
- What is the thermal budget on the mirror we can consume?
- Baffles additionally needed beside and inside CP  
→ acceptable height? 10 K max and actively cooled acceptable regarding noise?
