Composite Higgs Models

$$\frac{m_H^2}{\Lambda_{\text{SM}}^2} \sim 10^{-28} \lll 1 \rightarrow \text{Naturalness problem}$$

- Investigations into the fundamental nature and origin of the Higgs boson are among the topical subjects in theoretical physics.
- Because of the approximate (explicitly and spontaneously broken) scale-invariant nature of the SM theory, the Higgs boson itself is in fact a dilaton, the pseudo-Nambu-Goldstone boson associated with dilatations.
- The Higgs being a composite object with a compositeness scale of TeV order, is one of the few options for “Naturally” generating its mass.

Scale transformations

$$\mathcal{L} = \sum_i g_i(\mu) \mathcal{O}_i(x), \quad (1)$$

with $[\mathcal{O}_i] = d_i$. The content of the RG equations is summarized by assigning the transformations laws

$$\begin{aligned} \mathcal{O}_i(x) &\rightarrow e^{\lambda d_i} \mathcal{O}_i(e^\lambda x), \\ \mu &\rightarrow e^{-\lambda} \mu, \end{aligned}$$

under scale transformations $x^\mu \rightarrow e^\lambda x^\mu$.

If $d_i = 4$ and $\beta_i = 0$, the theory is scale invariant.

A simple way of incorporating non-linearly realized scale invariance is to add a field $\chi(x)$ that serves as a conformal compensator.

$$\chi(x) \rightarrow e^\lambda \chi(e^\lambda x),$$

We need to make the replacement

$$g_i(\mu) \rightarrow g_i \left(\mu \frac{\chi}{f} \right) \left(\frac{\chi}{f} \right)^{4-d_i},$$

Here $f = \langle \chi \rangle$ is the order parameter for scale symmetry breaking, determined by the dynamics of the underlying strong sector.

$$\chi(x) = f e^{\sigma(x)/f},$$

which transforms non-linearly under scale transformations,
 $\lambda : \sigma(x)/f \rightarrow \sigma(e^\lambda x)/f + \lambda$. One can also define $\bar{\chi}(x) = \chi(x) - f$.

Conformal transition

In AdS/CFT correspondence, there is the notion of BF bound. An operator with a complex dimension in CFT corresponds to fields in AdS with mass below the BF band.

Following [Kaplan et al. '09] and [Gorbenko et al. '18], there may be a range of values in the parameter space of the theory that the operator \mathcal{O}_g , dual to a field in the gravity side, becomes marginal, and develops a complex dimension. This will be a signal for the end of conformality.

6d garvity action

$$\mathcal{S}_6 = \mathcal{S}_6^{(bulk)} + \sum_{i=1,2} \mathcal{S}_{5,i} ,$$

$$\mathcal{S}_6^{(bulk)} = \int d^6x \sqrt{-\hat{g}_6} \left\{ \frac{\mathcal{R}_6}{4} - \frac{1}{2} \hat{g}^{\hat{M}\hat{N}} \partial_{\hat{M}} \phi \partial_{\hat{N}} \phi - \mathcal{V}_6(\phi) \right\} ,$$

$$\mathcal{S}_{5,i} = (-)^i \int d^5x \sqrt{-\tilde{g}} \left\{ \frac{\mathcal{K}}{2} + \lambda_i(\phi) + f_i \left(\tilde{g}^{\hat{M}\hat{N}} \right) \right\} \Big|_{\rho=\rho_i} ,$$

$\rho_1 < \rho < \rho_2$ and the he space-time index is $\hat{M} = 0, 1, 2, 3, 5, 6$.

$$\mathcal{V}_6(\phi) = -5 - \frac{\Delta(5-\Delta)}{2} \phi^2 - \frac{5\Delta^2}{16} \phi^4 ,$$

Asymptotically in the UV, the dual field theory flows towards a CFT in 5 dimensions, deformed by the insertion of an operator \mathcal{O} with scaling dimension given by $\max(\Delta, 5 - \Delta)$.

The two parameters appearing in the solution of the corresponding second-order classical equations correspond in field-theory terms to the coupling and condensate associated with \mathcal{O} .

Dimensional reduction to five dimensions

$$ds_6^2 = e^{-2\chi} dx_5^2 + e^{6\chi} (d\eta + \chi_M dx^M)^2,$$

where the space-time index is $M = 0, 1, 2, 3, 5$. The reduced action then becomes

$$\begin{aligned} S_5^{(bulk)} = \int d^5x \sqrt{-g_5} \left\{ \frac{R}{4} - \frac{1}{2} g^{MN} \left[6 \partial_M \chi \partial_N \chi + \partial_M \phi \partial_N \phi \right] - e^{-2\chi} \mathcal{V}_6(|\phi|) \right. \\ \left. - \frac{1}{16} e^{8\chi} g^{MP} g^{NQ} F_{MN}^{(\chi)} F_{PQ}^{(\chi)} \right\}, \end{aligned}$$

We consider background solutions in which $\chi_M = 0$, while the metric g_{MN} , ϕ , and χ depend on the radial coordinate only. The metric in five dimensions takes the domain-wall (DW) form

$$ds_5^2 = dr^2 + e^{2A(r)} dx_{1,3}^2 = e^{2\chi(\rho)} d\rho^2 + e^{2A(\rho)} dx_{1,3}^2,$$

with $d\rho = e^{-\chi} dr$.

UV expansions

$$\rho \rightarrow +\infty, \quad \phi = 0 \quad \text{critical point of } \mathcal{V}_6, \quad \chi \simeq \frac{1}{3}\rho, \quad A \simeq \frac{4}{3}\rho$$

We classify all the solutions in terms of a power expansion in the small parameter $z \equiv e^{-\rho}$. The expansion depends on five free parameters.

$$\phi(z) = \phi_J z^{\Delta_J} + \cdots + \phi_V z^{\Delta_V} + \cdots,$$

$$\chi(z) = \chi_U - \frac{1}{3} \log(z) + \cdots + (\chi_5 + \cdots) z^5 + \cdots,$$

$$A(z) = A_U - \frac{4}{3} \log(z) + \cdots.$$

Background solutions

Confining solutions The confining solutions are such that the circle parametrised by η shrinks to zero size at some point ρ_o of the radial direction ρ and there is no conical singularity. For small $(\rho - \rho_o)$, we find that such solutions have the following form

$$\begin{aligned}\phi(\rho) &= \phi_I - \frac{1}{16} \Delta \phi_I (20 + \Delta (5\phi_I^2 - 4)) (\rho - \rho_o)^2 + \mathcal{O}((\rho - \rho_o)^2) , \\ \chi(\rho) &= \chi_I + \frac{1}{3} \log(\rho - \rho_o) + \mathcal{O}((\rho - \rho_o)^4) , \\ A(\rho) &= A_I + \frac{1}{3} \log(\rho - \rho_o) + \mathcal{O}((\rho - \rho_o)^2) ,\end{aligned}$$

Singular domain-wall solutions They obey the DW ansatz $A = 4\chi = \frac{4}{3}\mathcal{A}$. In six dimensions, they take the form of Poincaré domain walls.

$$\begin{aligned}\phi(\rho) &= \phi_I - \sqrt{\frac{2}{5}} \log(\rho - \rho_o) + \mathcal{O}((\rho - \rho_o)^2) , \\ \mathcal{A}(\rho) &= \frac{1}{5} \log(\rho - \rho_o) + \mathcal{O}((\rho - \rho_o)^2) .\end{aligned}$$

The system of equations is symmetric under the change $\phi \rightarrow -\phi$, hence a second branch of solutions can be obtained by just changing the sign of ϕ . **These solutions are singular at the end of space.**

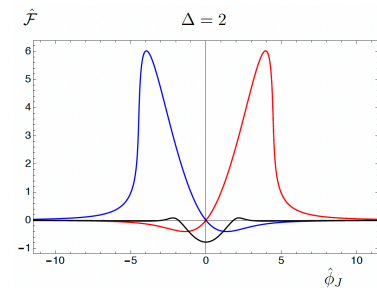

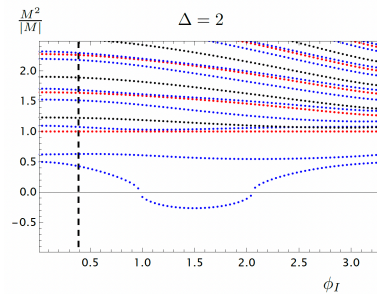

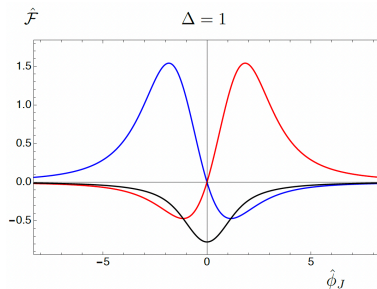

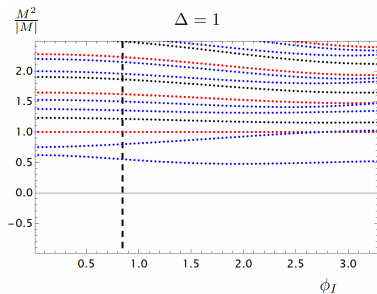

The free energy density is given by the following expression:

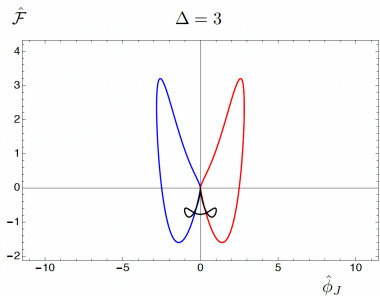

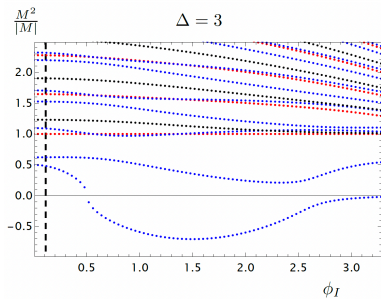

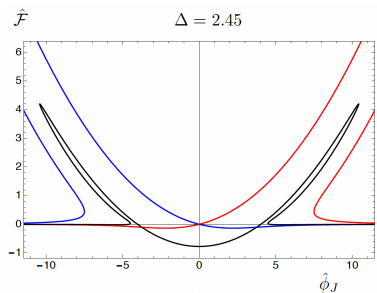

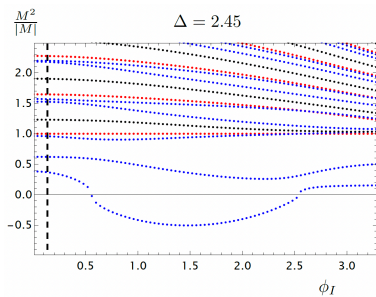

$$\mathcal{F} = - \lim_{\rho_2 \rightarrow +\infty} e^{4A-\chi} \left(\frac{3}{2} \partial_\rho A + \mathcal{W}_2 \right) \Big|_{\rho_2},$$

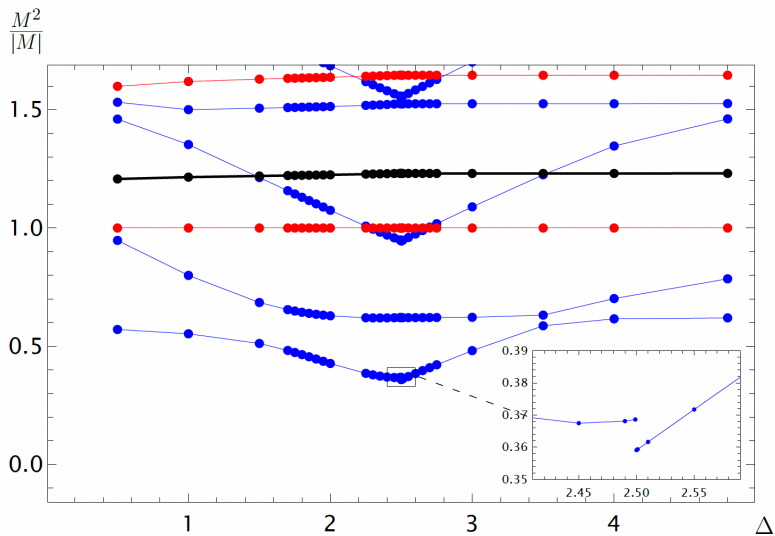

For example, for $\Delta < 5/2$, the free energy density is

$$\mathcal{F} = -\frac{1}{40} e^{4A_U - \chi_U} \left(16\Delta \left(\frac{5}{2} - \Delta \right) \phi_J \phi_V - 75\chi_5 \right),$$

Results

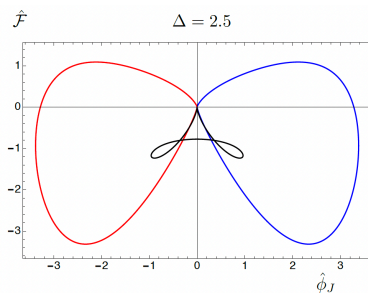

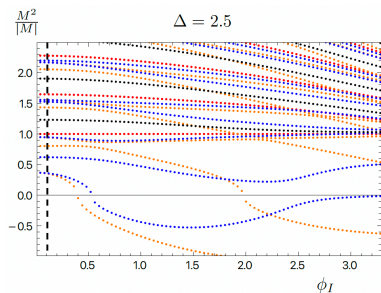

Summary and Outlook

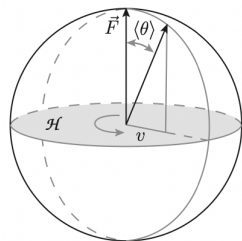

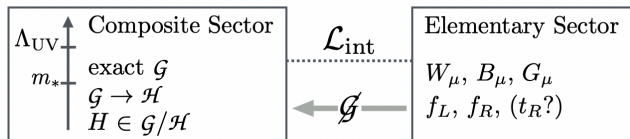

- We studied the mass spectrum of bosonic states in the field theory. The lightest state in this spectrum is a scalar particle.
- Along the confining branch of solutions, we find the presence of a tachyonic instability. In a region of parameter space nearby the tachyonic one, the lightest scalar particle can be interpreted as an approximate dilaton,
- We also computed the free energy. We find that both the dilatonic and tachyonic regions are hidden behind a first-order phase transition,
- The (approximate) dilaton appears in metastable solutions. Yet, the mass of the lightest state, computed close to the phase transition, is (mildly) suppressed when Δ is near $5/2$.
- The class of models analysed here does not cover all possible realisations of confining field theories and can be improved by considering top-down models
- We can further extend this six-dimensional model in the complementary context of composite Higgs models.

Thank you

Probe Approximation

Vacuum misalignment

$\mathcal{G} \rightarrow \mathcal{H}$ spontaneous breaking \rightarrow massless NGB's in the coset \mathcal{G}/\mathcal{H}

$$G_{EW} = SU(2)_L \times U(1)_Y \subseteq \mathcal{H}$$

G is large enough to contain at least one Higgs doublet in the coset
