Outline

- The simplified model
- The multilepton problem
 - Methodology
 - The anatomy of the anomalies
- A possible candidate of S
 - $\gamma\gamma$, $Z\gamma$ and ll +MET results
 - Prospects for Run 3

The Simplified Model and 2HDM+S

The simplified Model (from Run I)

- 1. The starting point of the hypothesis is the existence of a boson, H, that contains Higgs-like interactions, with a mass in the range 250-280 GeV**
- 2. In order to avoid large quartic couplings, incorporate a mediator scalar, S, that interacts with the SM and Dark Matter.**
- 3. Dominance of $H \rightarrow Sh, SS$ decay over other decays**

(a) Gluon fusion (ggF).

$$\mathcal{L}_{\text{int}} \supset -\beta_g \frac{m_t}{v} t\bar{t}H + \beta_V \frac{m_V^2}{v} g_{\mu\nu} V^\mu V^\nu H$$

$$\mathcal{L}_{HhS} = -\frac{1}{2} v \left[\lambda_{hhS} hhS + \lambda_{hSS} hSS + \lambda_{HHS} HHS + \lambda_{HSS} HSS + \lambda_{HhS} HhS \right],$$

The Decays of H

- In the general case, H can have couplings as those displayed by a Higgs boson in addition to decays involving the intermediate scalar and Dark Matter

$$H \rightarrow WW, ZZ, q\bar{q}, gg, Z\gamma, \gamma\gamma, \chi\chi$$
$$+ H \rightarrow SS, Sh, hh$$

Dominant decays

Diboson decay

$$H \rightarrow h(+X), S(+X)$$

The 2HDM+S

Eur. Phys. J. C (2016) 76:580

Introduce singlet real scalar, S .

2HDM potential, $\mathcal{V}(\Phi_1, \Phi_2)$

2HDM+S potential

$$\begin{aligned} &= m_1^2 \Phi_1^\dagger \Phi_1 + m_2^2 \Phi_2^\dagger \Phi_2 - m_{12}^2 (\Phi_1^\dagger \Phi_2 + \text{h.c.}) \\ &+ \frac{1}{2} \lambda_1 (\Phi_1^\dagger \Phi_1)^2 + \frac{1}{2} \lambda_2 (\Phi_2^\dagger \Phi_2)^2 \\ &+ \lambda_3 (\Phi_1^\dagger \Phi_1) (\Phi_2^\dagger \Phi_2) + \lambda_4 |\Phi_1^\dagger \Phi_2|^2 \\ &+ \frac{1}{2} \lambda_5 \left[(\Phi_1^\dagger \Phi_2)^2 + \text{h.c.} \right] \\ &+ \left\{ \left[\lambda_6 (\Phi_1^\dagger \Phi_1) + \lambda_7 (\Phi_2^\dagger \Phi_2) \right] \Phi_1^\dagger \Phi_2 + \text{h.c.} \right\} \end{aligned}$$

$$\begin{aligned} &\mathcal{V}(\Phi_1, \Phi_2) + \frac{1}{2} m_{S_0}^2 S^2 + \frac{\lambda_{S_1}}{2} \Phi_1^\dagger \Phi_1 S^2 \\ &+ \frac{\lambda_{S_2}}{2} \Phi_2^\dagger \Phi_2 S^2 + \frac{\lambda_{S_3}}{4} (\Phi_1^\dagger \Phi_2 + \text{h.c.}) S^2 \\ &+ \frac{\lambda_{S_4}}{4!} S^4 + \mu_1 \Phi_1^\dagger \Phi_1 S + \mu_2 \Phi_2^\dagger \Phi_2 S \\ &+ \mu_3 \left[\Phi_1^\dagger \Phi_2 + \text{h.c.} \right] S + \mu_S S^3. \end{aligned}$$

Out of considerations of simplicity, assume S to be Higgs-like, which is not too far fetched.

The model leads to rich phenomenology. Of particular interest are multilepton signatures

S. No.	Scalars	Decay modes
D.1	h	$b\bar{b}, \tau^+\tau^-, \mu^+\mu^-, s\bar{s}, c\bar{c}, gg, \gamma\gamma, Z\gamma, W^+W^-, ZZ$
D.2	H	D.1, hh, SS, Sh
D.3	A	D.1, $t\bar{t}, Zh, ZH, ZS, W^\pm H^\mp$
D.4	H^\pm	$W^\pm h, W^\pm H, W^\pm S$
D.5	S	D.1, $\chi\chi$

Scalar	Production mode	Search channels
H	$gg \rightarrow H, Hjj$ (ggF and VBF)	Direct SM decays as in Table 1 $\rightarrow SS/Sh \rightarrow 4W \rightarrow 4\ell + E_T^{\text{miss}}$ $\rightarrow hh \rightarrow \gamma\gamma b\bar{b}, b\bar{b}\tau\tau, 4b, \gamma\gamma WW$ etc. $\rightarrow Sh$ where $S \rightarrow \chi\chi \implies \gamma\gamma, b\bar{b}, 4\ell + E_T^{\text{miss}}$
	$pp \rightarrow Z(W^\pm)H$ ($H \rightarrow SS/Sh$)	$\rightarrow 6(5)l + E_T^{\text{miss}}$ $\rightarrow 4(3)l + 2j + E_T^{\text{miss}}$ $\rightarrow 2(1)l + 4j + E_T^{\text{miss}}$
	$pp \rightarrow t\bar{t}H, (t + \bar{t})H$ ($H \rightarrow SS/Sh$)	$\rightarrow 2W + 2Z + E_T^{\text{miss}}$ and b -jets $\rightarrow 6W \rightarrow 3$ same sign leptons + jets and E_T^{miss}
H^\pm	$pp \rightarrow tH^\pm$ ($H^\pm \rightarrow W^\pm H$)	$\rightarrow 6W \rightarrow 3$ same sign leptons + jets and E_T^{miss}
	$pp \rightarrow tbH^\pm$ ($H^\pm \rightarrow W^\pm H$)	Same as above with extra b -jet
	$pp \rightarrow H^\pm H^\mp$ ($H^\pm \rightarrow HW^\pm$)	$\rightarrow 6W \rightarrow 3$ same sign leptons + jets and E_T^{miss}
	$pp \rightarrow H^\pm W^\pm$ ($H^\pm \rightarrow HW^\pm$)	$\rightarrow 6W \rightarrow 3$ same sign leptons + jets and E_T^{miss}
A	$gg \rightarrow A$ (ggF)	$\rightarrow t\bar{t}$ $\rightarrow \gamma\gamma$
	$gg \rightarrow A \rightarrow ZH$ ($H \rightarrow SS/Sh$)	Same as $pp \rightarrow ZH$ above, but with resonance structure over final state objects
	$gg \rightarrow A \rightarrow W^\pm H^\mp$ ($H^\mp \rightarrow W^\mp H$)	$6W$ signature with resonance structure over final state objects

Multi-lepton final states

It is paramount to remark that the excesses are seen in final states that were predicted 2015/2016 on the basis of a simplified model and not the result of scan of the available phase-space. Additionally, the parameters of the model were fixed then leaving only one degree of freedom: normalization. Thus, no look-elsewhere effects in parameter or phase-space

$$pp \rightarrow H \rightarrow Sh$$

$$\rightarrow l^+ l^- + X$$

Expect di-leptons ($m_{ll} < 100$ GeV) with jets and b-jets with rates comparable to that of the SM Higgs boson

Top associated Higgs production (Multi-lepton final states)

$$A \rightarrow t\bar{t}, ZH$$

$$H \rightarrow SS, Sh$$

Reduced cross-section of $t\bar{t}H+tH$ is compensated by di-boson, (SS , Sh) decay and large $\text{Br}(S \rightarrow WW)$. Production of same sign leptons, three leptons is enhanced. Enhanced tH cross-section

Produces SS 2l, 3l with b-jets, including 3 b-jets

Explains anomalously large $t\bar{t}W+t\bar{t}h+4t$ cross-sections seen by ATLAS and CMS

Methodology

(to avoid biases and look-else-where effects)

Based Higgs p_T , hh, tth, VV in Run 1
Eur. Phys. J. C (2016) 76:580

Model defined and predictions made for
multilepton excesses

Multi-lepton excesses in Run 1 and few
Run 2 results available in 2017

J.Phys.G 45 (2018) 11, 115003

Model parameters fixed in 2017 with
 $m_H=270$ GeV, $m_S=150$ GeV,
S treated as SM Higgs-like,
dominance of $H \rightarrow Sh, SS$

Fixed final states and phase-space
defined by fixed model parameters.
NO tuning, NO scanning

Update same final states with
more data in Run 2

Study new final states where
excesses predicted and data
available in Run 1 and Run 2
(e.g., SS0b, 3l0b, ZW0b)

J.Phys. G46 (2019) no.11, 115001

JHEP 1910 (2019) 157

Chin.Phys.C 44 (2020) 6, 063103

Physics Letters B 811 (2020) 135964

Eur.Phys.J.C 81 (2021) 365

BSM inputs to the fit

- The following assumptions are made:
 - a. The masses of H and S are fixed to $m_H = 270$ GeV and $m_S = 150$ GeV
 - b. The only significant production mechanisms of H come from the t - t - H Yukawa coupling:
 - Gluon fusion
 - Top associated production
 - c. The Yukawa coupling is scaled away from the SM Higgs-like value by the free parameter β_g
 - d. The BR of $H \rightarrow Sh$ is fixed to 100%
 - e. The BRs of S are Higgs-like
- Therefore, the only free parameter in the fits is β_g^2

Combination of fit results (2019)

- **Simultaneous fit for all measurements:**
- **To the right: (-2 log) profile likelihood ratio for each individual result and the combination of them all**
- **The significance for each fit is calculated as**

$$\sqrt{-2 \log \lambda(0)}$$

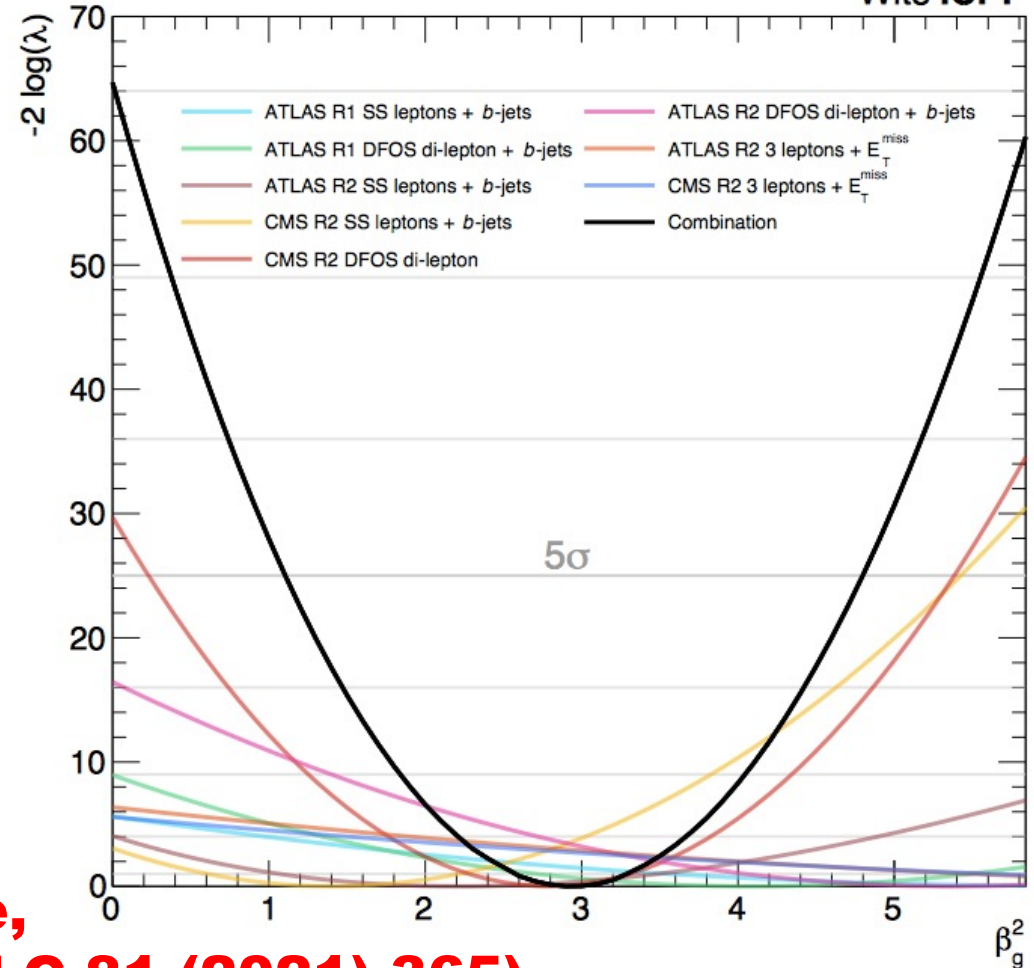

- **Best-fit: $\beta_g^2 = 2.92 \pm 0.35$**
- **Corresponds to 8.04σ**

Excesses have been growing since, and new have emerged (Eur.Phys.J.C 81 (2021) 365)

Interpretation: Measure of the inability of current MC tools to describe multiple-lepton data and how a simplified model with $H \rightarrow Sh$ is able to capture the effect with one parameter

JHEP 1910 (2019) 157

Wits ICPP

Is the discrepancy due to $t\bar{t}$ events?

$$p_{T\ell} > 25 \text{ GeV}$$

$$p_{Tb} > 25 \text{ GeV}$$

$$N_{bjet} \geq 1$$

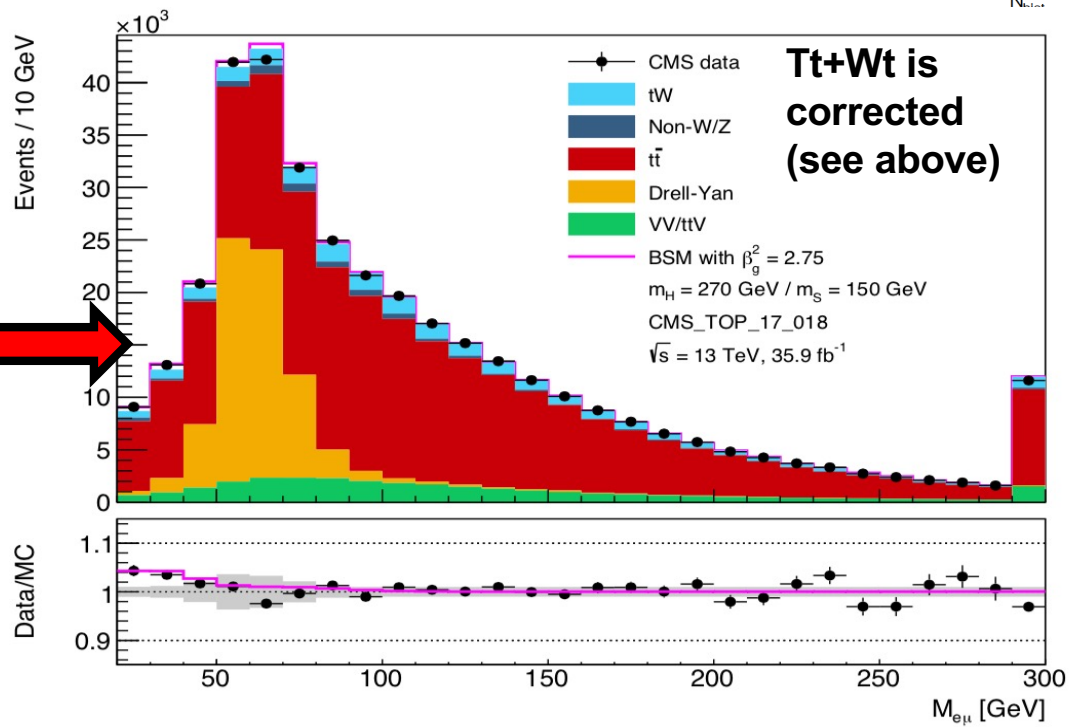

Events / 20 GeV

MC/Data

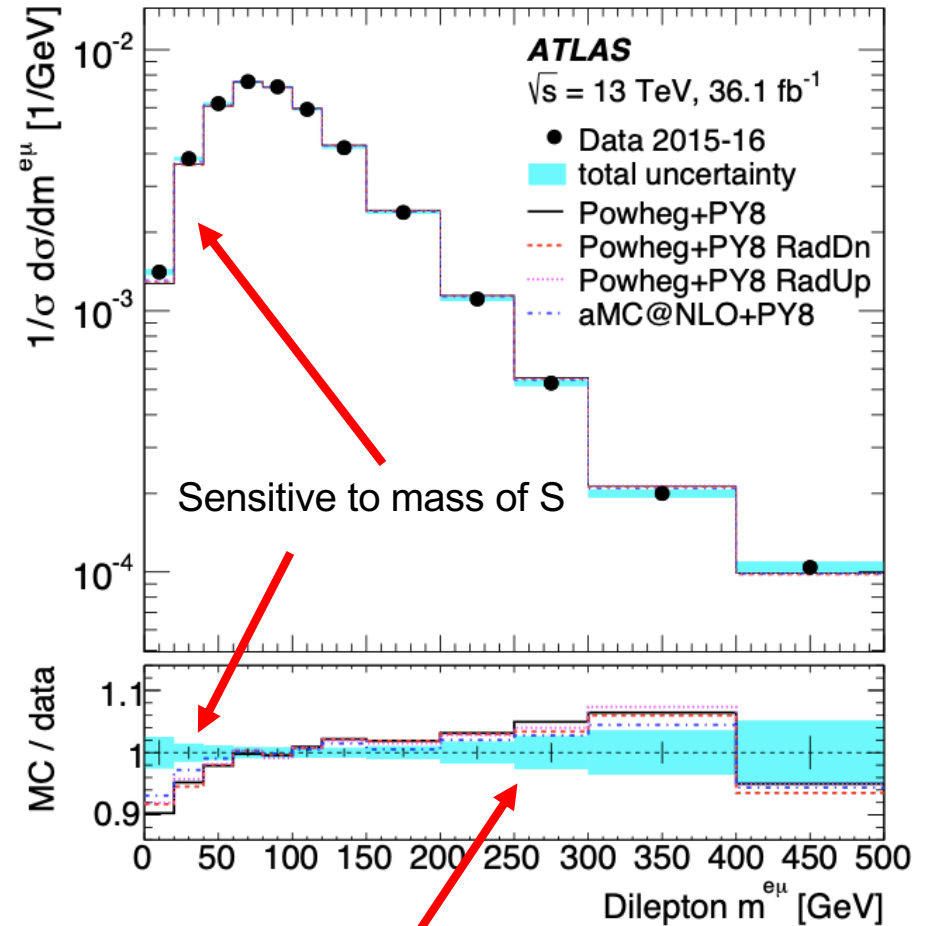

- Poor modeling of POWHEG + Pythia8 distribution is improved through reweighting
- We fix the normalisation of the SM by scaling it to the data in the region $m_{ll} > 110$ GeV
 - A normalisation systematic of 3% is applied to all but DY
 - DY systematic = 6.8%. 3% systematic on m_{ll} shape in top
 - The fit is done to the region below 110 GeV
- Fit results:
 - $\beta_g^2 = 2.79 \pm 0.52$
 - Fit is extremely well constrained

Negligible MC dependence, as m_{ll} shape comes from data

Used conservative assumption that $l+l+2b$ -jet final state is perfectly described by the SM. The discrepancy comes from events with $N_b < 2$. Excess unlikely due to tt

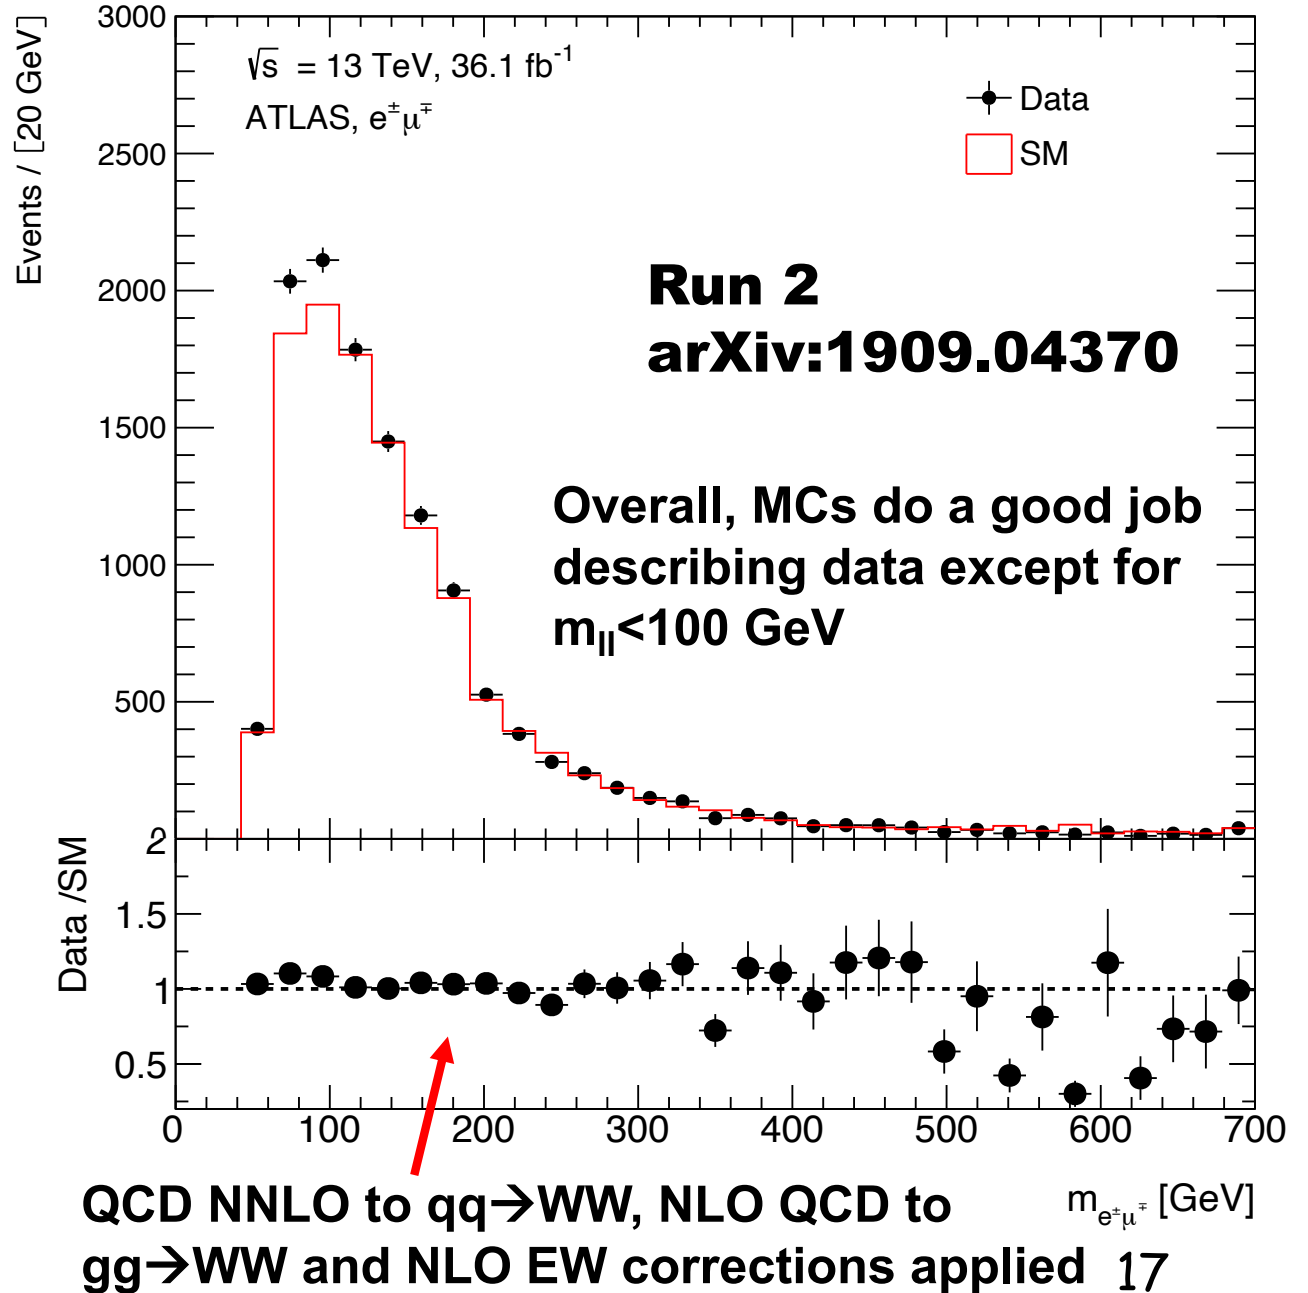

Residual discrepancies at high m_{ll} will be fixed with missing NNLO QCD and NLO EW corrections

Excess at low m_{ll} remains prevalent, indicating that effects seen in Run 1 were not statistical fluctuations. NNLO QCD corrections do not fix the issue (see Mitov et al.)

Run 1, J.Phys. G45 (2018) no.11, 115003

Excesses in di-leptons with full-jet veto not included above

From Run 1 multi-lepton excesses model-dependent prediction of $m_s = 150 \pm 5$ GeV

The anatomy of inclusive ttW at the LHC

S.Buddenbrock, R.Ruiz
and B.M.
Physics Letters B 811
(2020) 135964

Using fixed order computations at $O(\alpha_s^4\alpha)$ and NLO multi-jet matching yielding similar (10%-14%) corrections to the inclusive rate

Table 2: Total cross sections [fb] at $\sqrt{s} = 13$ TeV for the $pp \rightarrow t\bar{t}W^\pm jj$ process at LO, with scale and PDF uncertainties [%], for representative $p_T^{jk \text{ min}}$ with $|\eta^j| < 4.0$. Also shown is the decomposition according to partonic channel, for $q_V \in \{u, d\}$, $q \in \{u, d, c, s\}$, and $Q \in \{q, \bar{q}\}$.

Detailed studies that include the decomposition in partonic channels and differential distributions

Tension between data and predictions does not wane. For this process a complete NNLO computation is needed to reduce theory uncertainty

Anatomy of the multi-lepton anomalies

Final state	Characteristic	Dominant SM process	Significance
$l^+l^- + \text{jets, b-jets}$	$m_{ll} < 100 \text{ GeV}$, dominated by 0b-jet and 1b-jet	$tt+Wt$	$>5\sigma$
$l^+l^- + \text{full-jet veto}$	$m_{ll} < 100 \text{ GeV}$	WW	$\sim 3\sigma$
$l^\pm l^\pm$ & $l^\pm l^\pm + \text{b-jets}$	Moderate H_T	$ttW, 4t$	$>3\sigma$
$l^\pm l^\pm$ & $l^\pm l^\pm$ et al., no b-jets	In association with h	$Wh, (WWW)$	4.2σ
$Z(\rightarrow l^+l^-)+l$	$p_{TZ} < 100 \text{ GeV}$	ZW	$>3\sigma$

Anomalies cannot be explained by mismodelling of a particular process, e.g. $tt\bar{b}$ production alone.

**A possible
candidate of S**

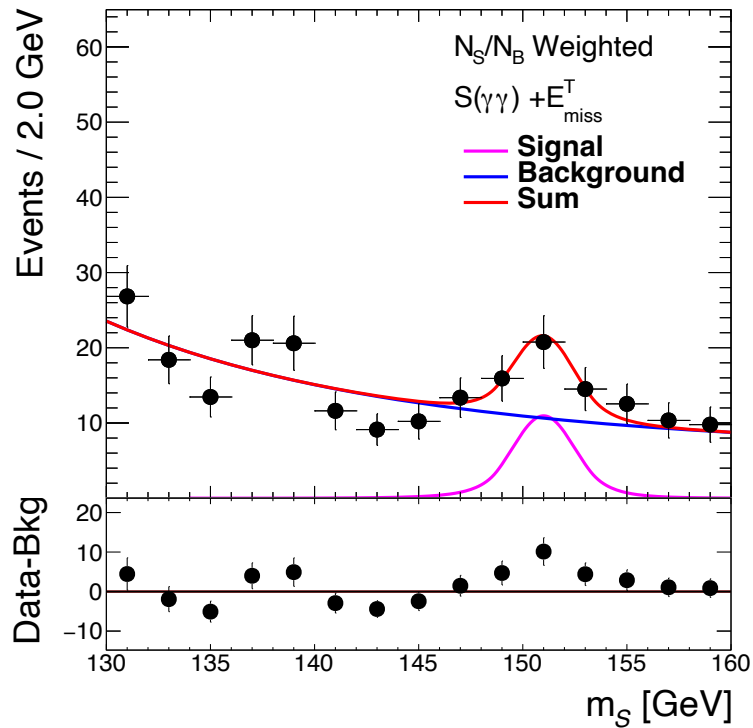

Procedure

(avoiding “cherry picking”)

- ❑ **Setting a well-defined procedure is essential to the integrity of a search. Scanning nullifies significance**
- ❑ **From the di-lepton anomalies: $m_h < m_s < 170$ GeV**
 - ❑ **It is critical that search be localized and motivated**
- ❑ **Focus on $\gamma\gamma$ and $Z\gamma$ decays**
- ❑ **As per the model that described the multi-lepton anomalies, we select final state according to di-boson signatures. S is produced via the decay of something heavier and not directly**
 - ❑ **Re-use Higgs boson data**
 - ❑ **Remove VBF and boosted topologies**
 - **Related to direct production**

From Run 1 multi-lepton excesses model-dependent prediction of $m_s = 150 \pm 5$ GeV

Analysis of publicly available $\gamma\gamma$, $Z\gamma$ spectra in associated production gives an excess at $m_S=151.5$ GeV.

Fiducial yields consistent with $H\rightarrow SS^*$ hypothesis with $m_H=270$ GeV, which is used for the extraction of significance.

Excess not seen in $S\rightarrow ZZ\rightarrow 4l$

Result is obtained with public results from the LHC experiments. Using a simplified model and two degrees of freedom and residual LEE global significance drops to 3.9σ at 151.5 GeV.

2022/03/11

Measurements of properties of the Higgs boson in the W boson pair decay channel in proton-proton collisions at
 $\sqrt{s} = 13$ TeV

The CMS Collaboration

Recently released $h \rightarrow WW \rightarrow \ell\ell + \text{MET}$ analysis present discrepancy with the data.

Here we to add $H \rightarrow SS^*$, with $S \rightarrow WW \rightarrow \ell\ell + \text{MET}$ to the SM processes. Using the simplified model with the mass fixed at $m_S = 151 \text{ GeV}$

Here we add $H \rightarrow SS^*$, with $S \rightarrow WW \rightarrow \ell\ell + \text{MET}$ to the SM processes. Using the simplified model with the mass fixed at $m_S = 151$ GeV

Extracted BSM signal strength consistent with the simplified model described above within statistical errors. Results point at somewhat higher jet-veto survival probability compared to the simplified model. This will be taken into account when performing combination with $\gamma\gamma$, $Z\gamma$ results described above

Global fits with ATLAS results in progress.

Abovementioned excess further motivates searches for bosons in asymmetric $\gamma\gamma b\bar{b}$ configurations not performed before at the LHC

Expect more than 7σ significance for one experiment with the Run 2 + Run 3 data sets.

Some tantalizing results around 96 GeV from LEP and CMS, not contradicted by ATLAS. Interesting to see what the full Run 2 data set has to say. Further motivates asymmetric searches $H \rightarrow SS'$...

Outlook and Conclusions

- ❑ **Discrepancies in multi-lepton final states at LHC w.r.t. current MCs are not statistical fluctuations**
 - ❑ **They appear in corners of the phase-space dominated by different processes** ($Wt/tt/4t$, VV , ttV , Vh , WWW)
 - **Hard to explain with MC mismodelling**
 - ❑ **Discrepancies interpreted with simplified model where $H \rightarrow SS$, S_h is treated as SM Higgs-like and one parameter is floated**
- ❑ **Features of the Higgs data from LHC agree with predictions the simplified model used here**
- ❑ **Analysis of $\gamma\gamma/Z\gamma$ spectra in associated production gives a large global excess around 151 GeV**
 - ❑ **Excess also appears in $ll + \text{MET}$ trans. mass spectrum**
 - ❑ **Motivates $H \rightarrow SS^*$, $S_h \rightarrow \gamma\gamma bb$ searches, where asymmetric configurations play an important role**

Additional Slides

For simplicity we will assume that the S decays like the SM Higgs boson

Masses in the 2HDM+S

$$\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix} = \mathbb{R} \begin{pmatrix} \rho_1 \\ \rho_2 \\ \rho_S \end{pmatrix},$$

Mass-matrix for the CP-even scalar sector will be modified with respect to 2HDM and that needs a 3 x 3 matrix (three mixing angles). Couplings are modified.

$$\mathbb{R} = \begin{pmatrix} c_{\alpha_1} c_{\alpha_2} & s_{\alpha_1} c_{\alpha_2} & s_{\alpha_2} \\ - (c_{\alpha_1} s_{\alpha_2} s_{\alpha_3} + s_{\alpha_1} c_{\alpha_3}) & c_{\alpha_1} c_{\alpha_3} - s_{\alpha_1} s_{\alpha_2} s_{\alpha_3} & c_{\alpha_2} s_{\alpha_3} \\ -c_{\alpha_1} s_{\alpha_2} s_{\alpha_3} + s_{\alpha_1} s_{\alpha_3} & - (c_{\alpha_1} s_{\alpha_3} + s_{\alpha_1} s_{\alpha_2} c_{\alpha_3}) & c_{\alpha_2} c_{\alpha_3} \end{pmatrix}$$

$$M_{\text{CP-even}}^2 = \begin{pmatrix} 2\lambda_1 v_1^2 - m_{12} \frac{v_2}{v_1} & m_{12} + \lambda_{345} v_1 v_2 & 2\kappa_1 v_1 v_S \\ m_{12} + \lambda_{345} v_1 v_2 & -m_{12} \frac{v_2}{v_1} + 2\lambda_2 v_2^2 & 2\kappa_2 v_2 v_S \\ 2\kappa_1 v_1 v_S & 2\kappa_2 v_2 v_S & \frac{1}{3} \lambda_S v_S^2 \end{pmatrix}$$

$$\begin{aligned}
m_{H_1}^2 &= v_S \sin \alpha_2 [\lambda_7 v \cos \alpha_1 \cos \alpha_2 \cos \beta + \lambda_8 v \sin \alpha_1 \cos \alpha_2 \sin \beta + \lambda_6 v_S \sin \alpha_2], \\
m_{H_2}^2 &= (\cos \alpha_1 \cos \alpha_3 - \sin \alpha_1 \sin \alpha_2 \sin \alpha_3) \left[\cos \alpha_1 \cos \alpha_2 (\lambda_{345} v^2 \sin \beta \cos \beta - m_{12}^2) \right. \\
&\quad \left. + \sin \alpha_1 \cos \alpha_2 (m_{12}^2 \cot \beta + \lambda_2 v^2 \sin^2 \beta) + \lambda_8 v v_S \sin \alpha_2 \sin \beta \right], \\
m_{H_3}^2 &= (\sin \alpha_1 \sin \alpha_3 - \sin \alpha_2 \cos \alpha_1 \cos \alpha_3) \left[\cos \alpha_1 \cos \alpha_2 (m_{12}^2 \tan \beta + \lambda_1 v^2 \cos^2 \beta) \right. \\
&\quad \left. + \sin \alpha_1 \cos \alpha_2 (\lambda_{345} v^2 \sin \beta \cos \beta - m_{12}^2) + \lambda_7 v v_S \sin \alpha_2 \cos \beta \right]. \tag{2.17}
\end{aligned}$$

Perform scans after fixing masses of physical bosons ($m_{h_1}=125$ GeV, $m_{h_2}=140$, $m_{h_3}=270$ GeV, $m_A=600$ GeV, $m_{H^\pm}=600$ GeV) in addition to the constraints described in arXiv:1711.07874, including the signal Yukawa coupling strength of $\beta_g^2=1.38 \pm 0.22$ (translated into $\tan^2 \beta$)

Correlation plots for the three mixing angles and $\tan\beta$. Blue (red) points correspond to $\text{Br}(h \rightarrow \text{SM})$ within 10% (20%) of the SM h values (J.Phys. G46 (2019) no.11, 115001)

Results using N2HDECAY (arXiv:1612.01309) for one benchmark point

Impact of NNLO QCD in WW

The NNLO QCD corrections shift the m_{ll} spectrum towards larger values.

The discrepancy becomes larger in the region of interest with $m_{ll} < 100$ GeV

EW corrections are important at high p_T due to Sudakov logarithms. Effect is less than 1% for $m_{H^\pm} < 100$ GeV, where discrepancies are seen.

The HistFactory method

K. Cranmer, G. Lewis, L. Moneta, A. Shibata, and W. Verkerke, *HistFactory: A tool for creating statistical models for use with RooFit and RooStats*, CERN-OPEN-2012-016.

- **Constructs a likelihood function from template histograms**
- **Allows for a simple implementation of systematic uncertainties that affect normalisation and/or shape**

$$\mathcal{P}(n_{cb}, a_p | \phi_p, \alpha_p, \gamma_b) = \prod_{c \in \text{channels}} \prod_{b \in \text{bins}} \text{Pois}(n_{cb} | \nu_{cb}) \cdot G(L_0 | \lambda, \Delta_L) \cdot \prod_{p \in \mathbb{S} + \Gamma} f_p(a_p | \alpha_p)$$

In our case, each “channel” is a different measurement.

The Poisson probability for the “expected” and “observed” number of events per bin.

Functional form of luminosity and its variations (not necessary for us).

Functional form of systematic variation with nuisance parameter α_p .

3l with Z→ll (ZW cross-section)

CMS PAS SMP-18-002

Errors in the plot are dominated by the 15% uncertainty on normalization to account NLO/NNLO differences. The uncertainty of the shape is much smaller of order of few %

Systematics that will directly affect the shape

arXiv:1711.07874

JHEP 1910 (2019) 157

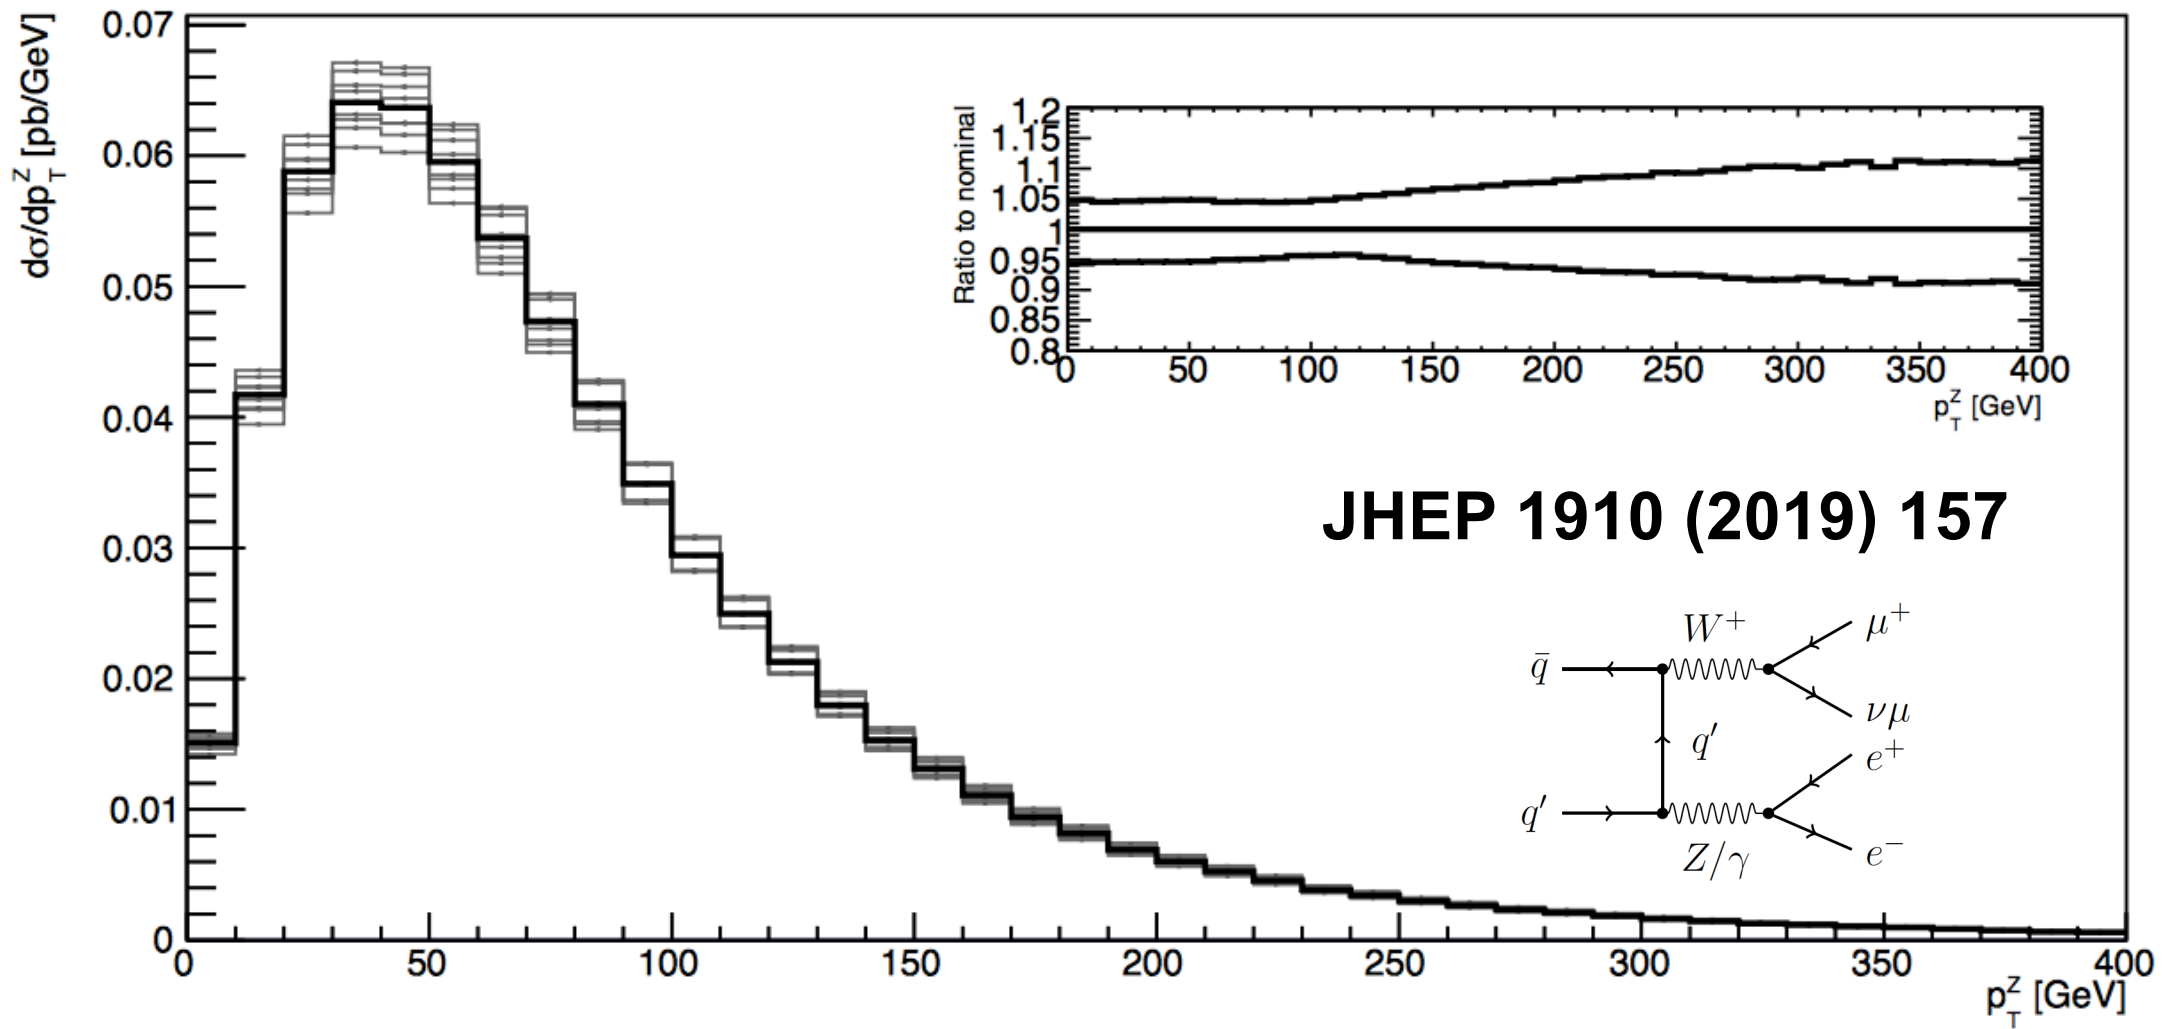

Figure 10: The effects of scale variations in the differential cross section of the SM WZ process as a function of the Z p_T . Here, aMC@NLO and Pythia 8 were used to generate the events. The thick black line represents the spectrum at the nominal scale, and each grey line is a variation of the scale. The insert shows the maximum and minimum relative deviations for all scale variations.

The fitting procedure

- **The RooStats workspace is made by HistFactory**
- **From the workspace, a profile likelihood ratio is calculated,**

$$\lambda(\beta_g^2) = \frac{L(\beta_g^2 | \hat{\theta})}{L(\hat{\beta}_g^2 | \hat{\theta})} \quad (\text{here } \theta \text{ denotes the nuisance parameters})$$

- **The best-fit value of β_g^2 is then calculated as the minimum of $-2\log(\lambda)$, with an error corresponding to a unit of deviation in this quantity from the best-fit point**
- **The significance is calculated as $\sqrt{-2 \log \lambda(0)}$, since $\beta_g^2 = 0$ corresponds to the SM-only hypothesis**

Is the discrepancy due to $t\bar{t}$ events?

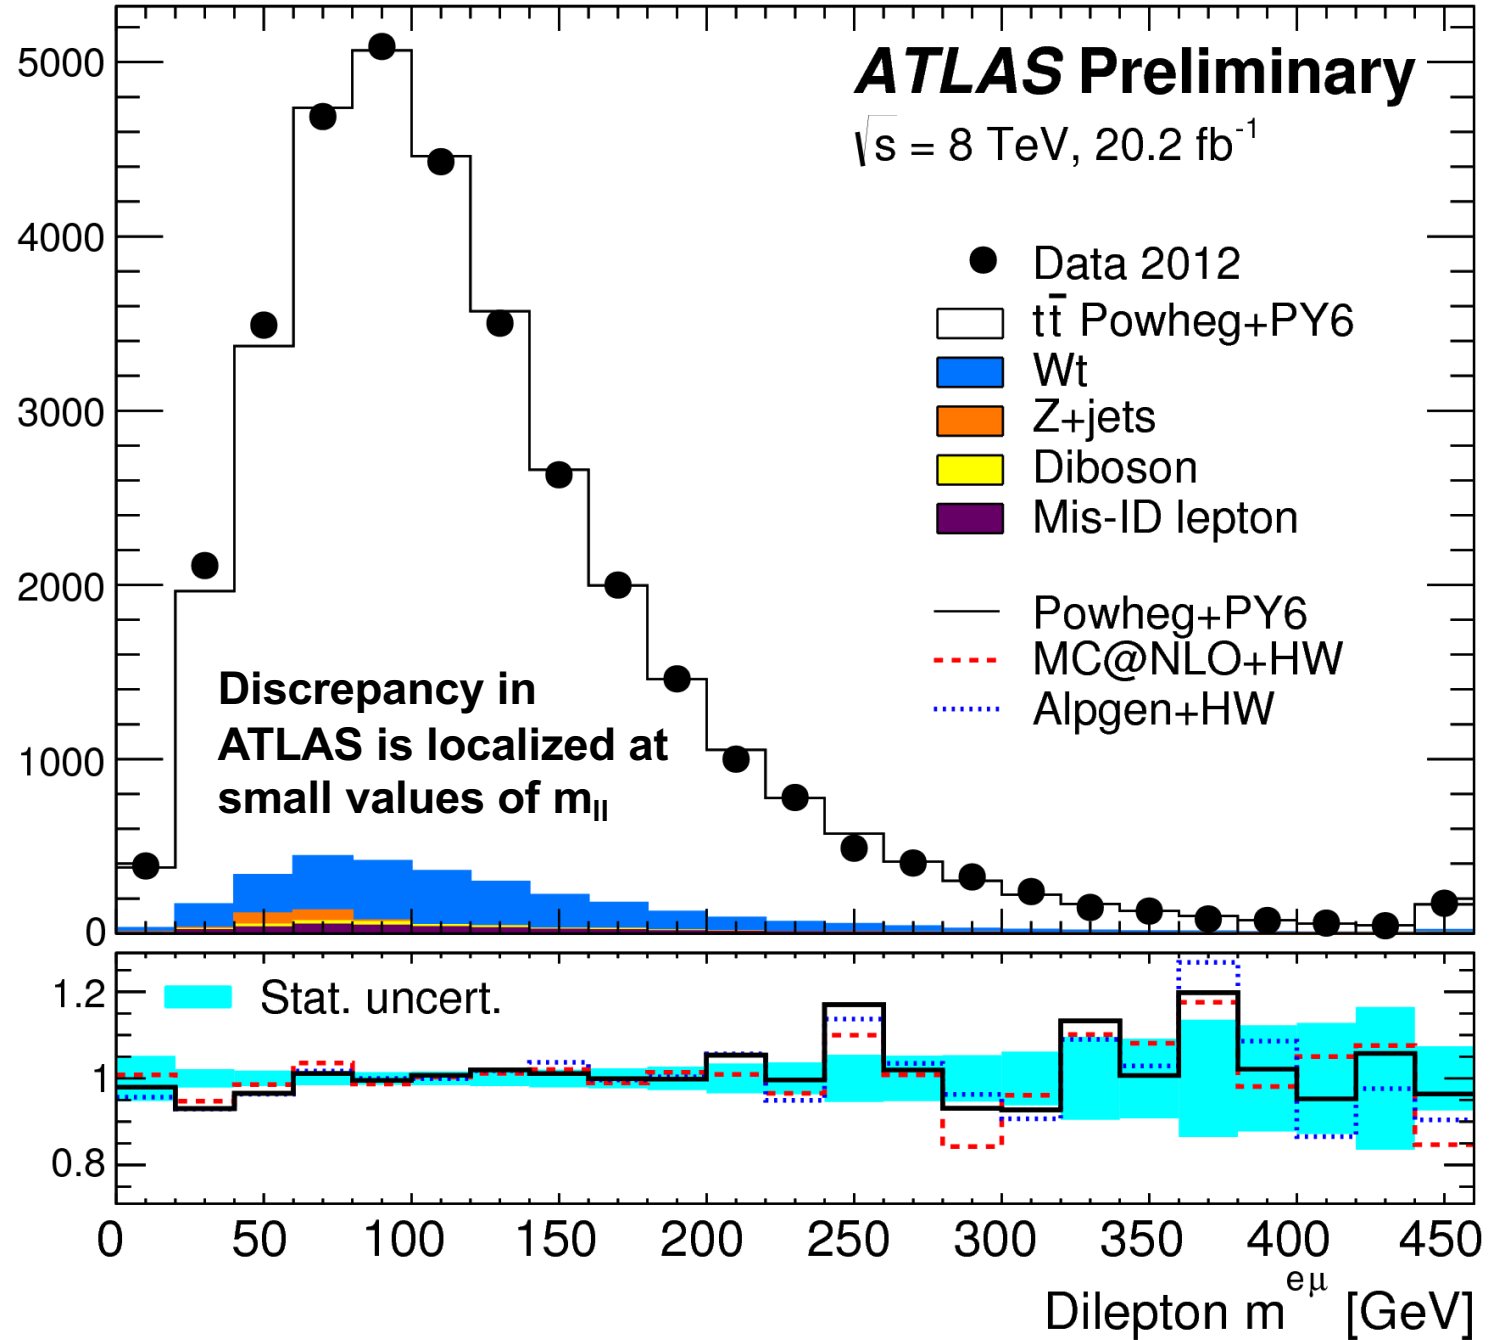

$$p_{T\ell} > 25 \text{ GeV}$$

$$p_{Tb} > 25 \text{ GeV}$$

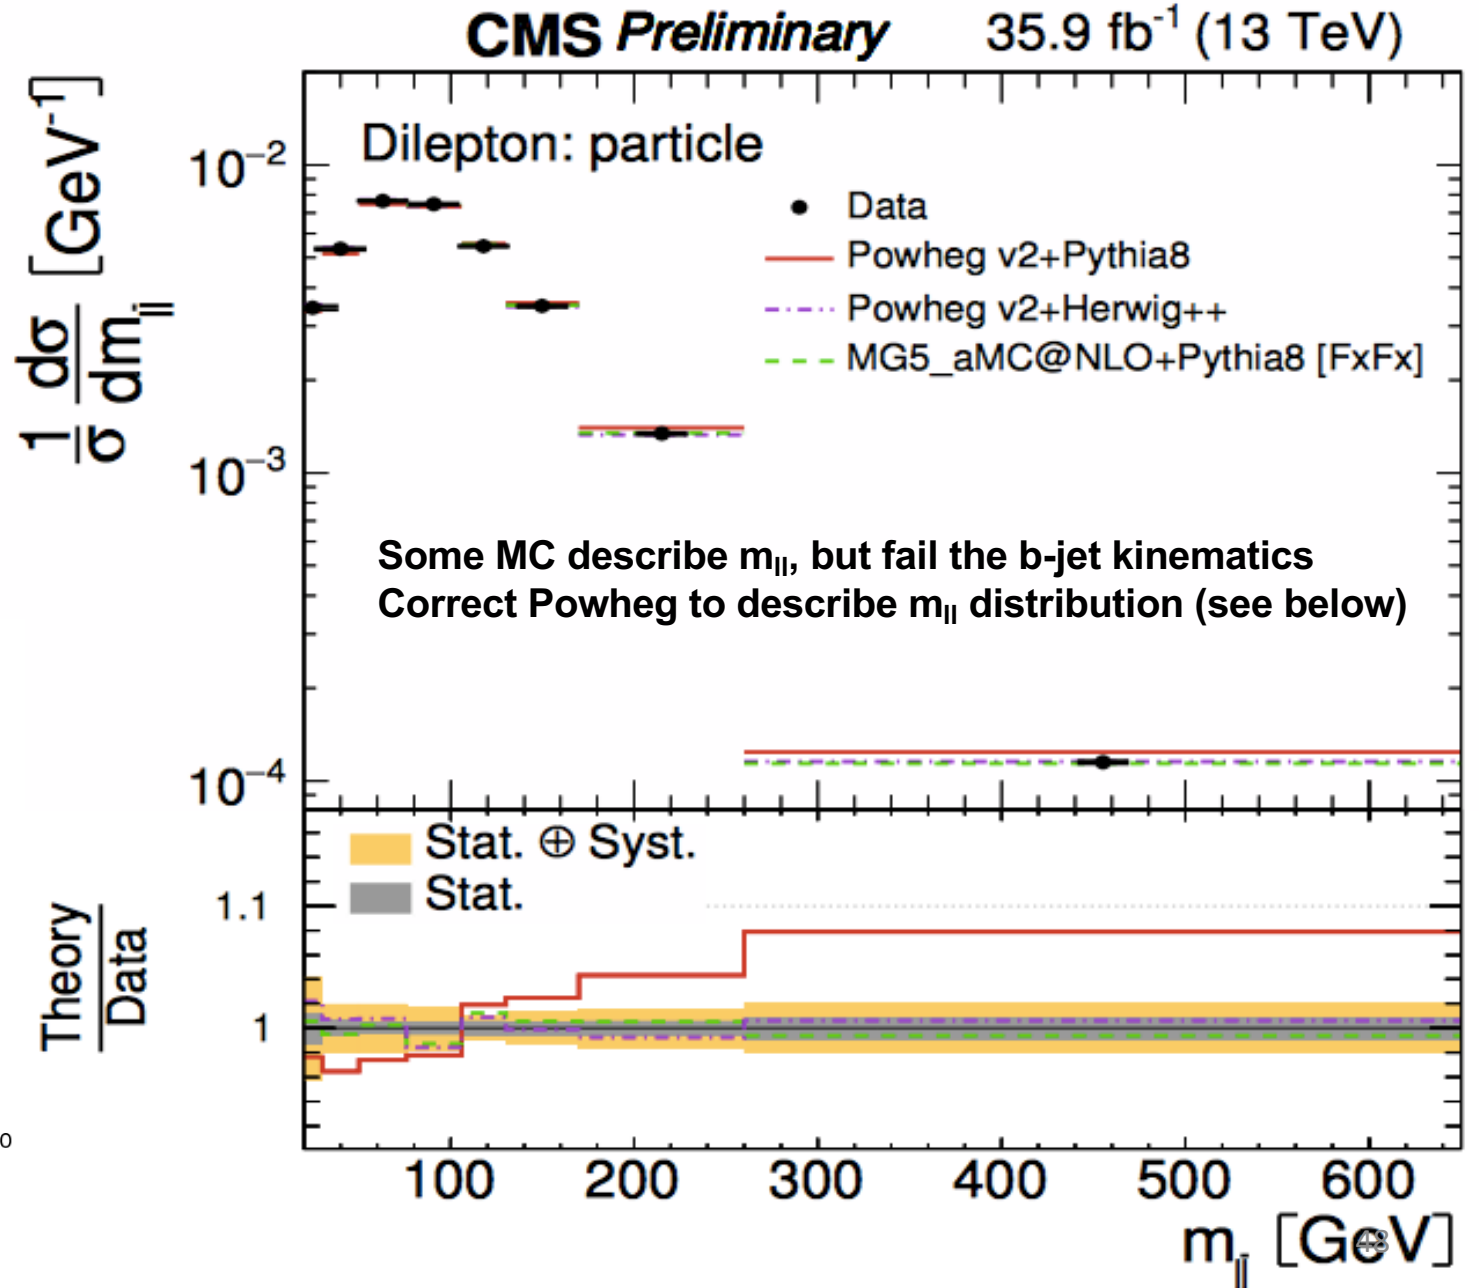

$$N_{bjet} \geq 1$$

Events / 20 GeV

MC/Data

**Event selection with exactly two leptons (e,μ),
m_{ll}>20 GeV and at least 2b-jets**

b-jet multiplicity is robust theoretically

Figure 9: Leptonic distributions produced by $t\bar{t}$ and tW processes (see text) as a function of the b -tagged jet multiplicity. The di-lepton invariant mass (left) and the transverse mass of the di-lepton and missing transverse energy system are displayed. Distributions are normalised to unity. The insert shows the ratio of the distributions with exclusive b -tagged jet bins relative to that obtained inclusively.

- Poor modeling of POWHEG + Pythia8 distribution is improved through reweighting
- We fix the normalisation of the SM by scaling it to the data in the region $m_{ll} > 110$ GeV
 - A normalisation systematic of 3% is applied to all but DY
 - DY systematic = 6.8%. 3% systematic on m_{ll} shape in top
 - The fit is done to the region below 110 GeV
- Fit results:
 - $\beta_g^2 = 2.79 \pm 0.52$
 - Fit is extremely well constrained

Negligible MC dependence, as m_{ll} shape comes from data

Used conservative assumption that $l+l+2b$ -jet final state is perfectly described by the SM. The discrepancy comes from events with $N_b < 2$. Excess unlikely due to tt

$$\Delta a_\mu = a_\mu^{\text{Exp}} - a_\mu^{\text{SM}} = 2.87(80) \times 10^{-9}$$

The Muon $g-2$ and the 2HDM+S

2HDM+S potential with fixed parameters from multi-lepton anomalies at the LHC

$$\begin{aligned}
 V(\Phi_1, \Phi_2, \Phi_S) &= m_{11}^2 |\Phi_1|^2 + m_{22}^2 |\Phi_2|^2 - m_{12}^2 (\Phi_1^\dagger \Phi_2 + \text{h.c.}) \\
 &+ \frac{\lambda_1}{2} (\Phi_1^\dagger \Phi_1)^2 + \frac{\lambda_2}{2} (\Phi_2^\dagger \Phi_2)^2 + \lambda_3 (\Phi_1^\dagger \Phi_1) (\Phi_2^\dagger \Phi_2) \\
 &+ \lambda_4 (\Phi_1^\dagger \Phi_2) (\Phi_2^\dagger \Phi_1) + \frac{\lambda_5}{2} \left[(\Phi_1^\dagger \Phi_2)^2 + \text{h.c.} \right] \\
 &+ \frac{1}{2} m_S^2 \Phi_S^2 + \frac{\lambda_6}{8} \Phi_S^4 + \frac{\lambda_7}{2} (\Phi_1^\dagger \Phi_1) \Phi_S^2 + \frac{\lambda_8}{2} (\Phi_2^\dagger \Phi_2) \Phi_S^2
 \end{aligned}$$

Consider extra degrees of freedom in the form of SM singlet vector-like fermions

$$\mathcal{L} \supset -y_{f'}^S \bar{l}_R \Phi_S f'_L - \sum_{i=1}^2 y_{f'}^i \bar{L}_l \Phi_i f'_R + \text{h.c.},$$

Dark matter annihilation.
Leptons, photons and protons
from the decays of S .

$2 \rightarrow 2$

Table 2: Overview of the selection defining the analysis categories.

Category	Number of leptons	Number of jets	Sub-categorization
ggH	2	-	(DF, SF) \times (0 jets, 1 jet, ≥ 2 jets)
VBF	2	≥ 2	(DF, SF)
VH2j	2	≥ 2	(DF, SF)
WHSS	2	≥ 1	(DF, SF) \times (0 jets, 1 jet)
WH3 ℓ	3	0	SF lepton pair with opposite or same sign
ZH3 ℓ	3	≥ 1	(1 jet, 2 jets)
ZH4 ℓ	4	-	(DF, SF)

Table 3: Summary of the selection used in different flavor ggH categories.

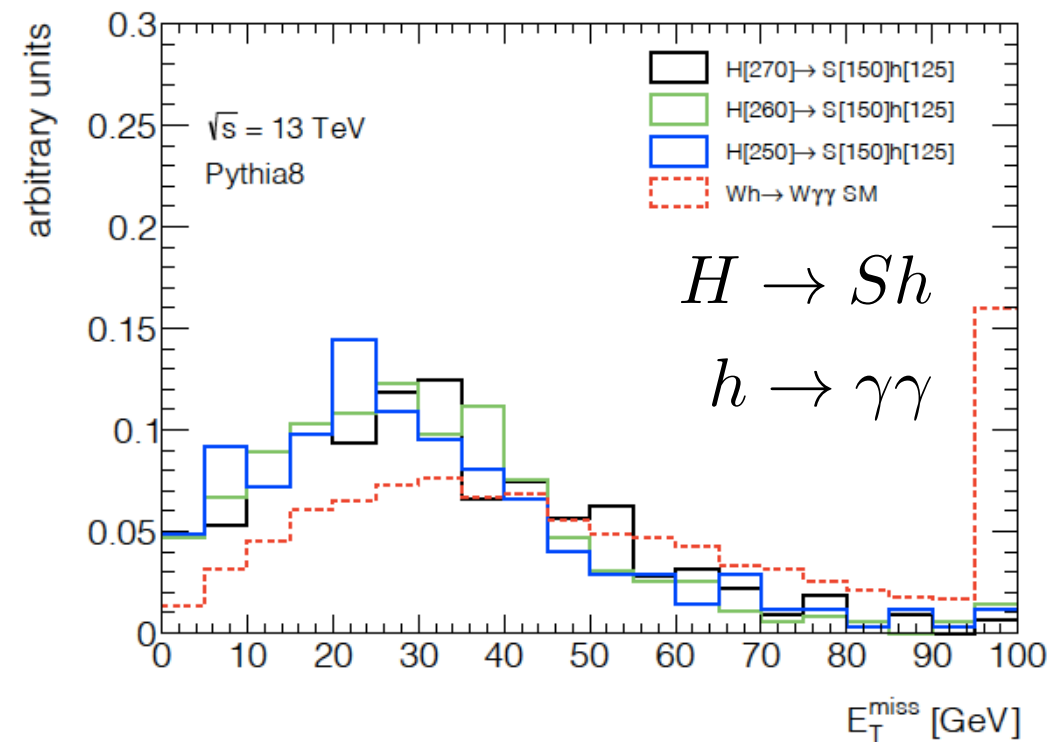

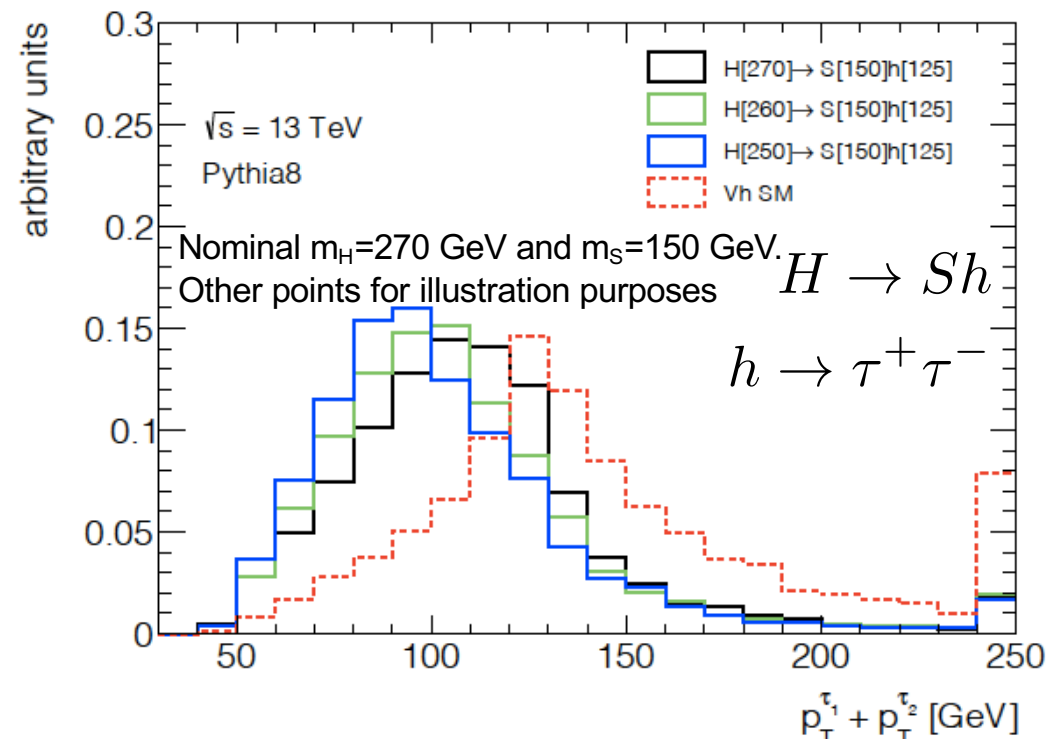

Category	Sub-categories	Selection
Global selection	-	$p_{T1} > 25 \text{ GeV}, p_{T2} > 10 \text{ GeV}$ (2016) or 13 GeV $p_T^{\text{miss}} > 20 \text{ GeV}, p_T^{\ell\ell} > 30 \text{ GeV}, m_{\ell\ell} > 12 \text{ GeV}$ $e\mu$ pair with opposite charge
0-jet ggH tagged	$\ell^\pm \ell^\mp, p_{T2} \leq 20 \text{ GeV}$	$m_T^H > 60 \text{ GeV}, m_T(\ell 2, p_T^{\text{miss}}) > 30 \text{ GeV}$ $p_{T2} \leq 20 \text{ GeV}$ No jet with $p_T > 30 \text{ GeV}$ No b-tagged jet with $p_T > 20 \text{ GeV}$
	Top CR	As SR, no m_T^H requirement, $m_{\ell\ell} > 50 \text{ GeV}$ At least 1 b-tagged jet with $20 \text{ GeV} < p_T < 30 \text{ GeV}$
	$\tau^+ \tau^-$ CR	As SR but with $m_T^H < 60 \text{ GeV}$ $30 \text{ GeV} < m_{\ell\ell} < 80 \text{ GeV}$
1-jet ggH tagged	$\ell^\pm \ell^\mp, p_{T2} \leq 20 \text{ GeV}$	$m_T^H > 60 \text{ GeV}, m_T(\ell 2, p_T^{\text{miss}}) > 30 \text{ GeV}$ $p_{T2} \leq 20 \text{ GeV}$ 1 jet with $p_T > 30 \text{ GeV}$ No b-tagged jet with $p_T > 20 \text{ GeV}$
	Top CR	As SR, no m_T^H requirement, $m_{\ell\ell} > 50 \text{ GeV}$ At least 1 b-tagged jet with $p_T > 30 \text{ GeV}$
	$\tau^+ \tau^-$ CR	As SR but with $m_T^H < 60 \text{ GeV}$ $30 \text{ GeV} < m_{\ell\ell} < 80 \text{ GeV}$
2-jet ggH tagged	SR	$m_T^H > 60 \text{ GeV}, m_T(\ell 2, p_T^{\text{miss}}) > 30 \text{ GeV}$ $p_{T2} \leq 20 \text{ GeV}$ At least 2 jets with $p_T > 30 \text{ GeV}$ No b-tagged jet with $p_T > 20 \text{ GeV}$ $m_{jj} < 65 \text{ GeV}$ or $105 \text{ GeV} < m_{jj} < 120 \text{ GeV}$
	Top CR	As SR, no m_T^H requirement, $m_{\ell\ell} > 50 \text{ GeV}$ At least 1 of the leading jets b-tagged
	$\tau^+ \tau^-$ CR	As SR but with $m_T^H < 60 \text{ GeV}$ $30 \text{ GeV} < m_{\ell\ell} < 80 \text{ GeV}$

Impact on Higgs Physics

The presence of a BSM signal of the type $H \rightarrow Sh$ would lead to:

- ❑ The presence of extra leptons in association with h . Affects the Wh measurement (Eur.Phys.J.C 81 (2021) 365)
- ❑ Distortion of Higgs p_T and rapidity (under study)

No tuning of model parameters performed. Look at fixed corners of the phase-space fixed with parameters of 2017.

Survey of LHC results on Vh ($V=W,Z$) production (Eur.Phys.J.C 81 (2021) 365)

The BSM ($H \rightarrow Sh$) signal appears at low p_{Th} and the SM signal is prevalent at larger p_{Th} (no tuning of parameters)

Include those results from ATLAS and CMS where no requirements on p_{Th} (or correlated observables) is not done or used in an MVA.

Those results where the final state is treated more “inclusively” display elevated signal strengths for Wh production:

$$\mu(Wh) = 2.41 \pm 0.37$$

This represents a 3.8σ deviation from the SM value of 1. BSM signal normalization less than expected from multilepton excesses assuming $Br(H \rightarrow Sh)=100\%$. Indicates that $Br(H \rightarrow SS) > Br(H \rightarrow Sh)$

CMS *Preliminary*

137 fb⁻¹ (13 TeV)

VH, H→WW

CMS-PAS-HIG-19-017

New results from CMS in the measurement of V_h , $h \rightarrow WW$ add to the anomalies reported in Eur.Phys.J.C 81 (2021) 365

Deviation from the SM becomes stronger with $p_{TV} < 150$ Gev

CMS Physics Analysis Summary

Search for the Higgs boson decay to $Z\gamma$ in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration

CMS observes what appears to be an upward fluctuation of the $h \rightarrow Z\gamma$ in the di-jet bin optimized for the measurement of Wh production. The Signal strength deviates from unity by 3.2σ .
