“the Charge”

“Seeing the K/D anomalies come and go, that has caused a lot of excitement as well as some confusion. Would you be willing to offer your perspectives on the current stand of flavor physics, of course in connection with your view for BSM.”

12/20 *Nature News* (LHCb Seminar @ CERN)

Although the latest result had been rumoured for months, its confirmation comes as a surprise, says Gino Isidori, a theoretical physicist at the University of Zurich who was at the CERN talk, because a coherent picture seemed to be emerging from related anomalies. This could have pointed to the existence of previously unseen elementary particles that affect the decay of *B* mesons. Isidori gives the LHCb collaboration credit for being “honest” in admitting that its previous analyses had problems, but he regrets that it took so long for the collaboration to find the issues.

“Just, please try to engage a broader audience.”

M. Mangano (“the diplomat”), 12/20 *CERN Courier*

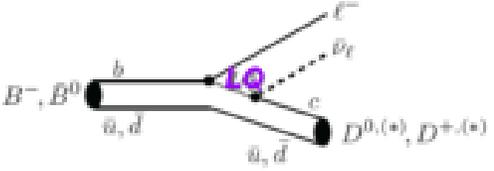

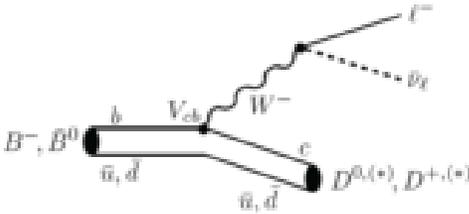

“That such anomalies could have been real shows how little we know about the deep origin of flavour symmetries and their relation with the Higgs, and highlights the key role of experimental guidance. ... The latest LHCb findings take nothing away from our mission to push further the boundary of our knowledge, and the search for anomalies goes on!”

The World After (in 2023)

Update of LHCb $R(K^{(*)})$:

- Simultaneous $R(K)$, $R(K^*)$ measurement with full stat.
- Increased signal purity and significance.
- Better background modelling.

Redefinition of q^2 regions.

Treatment of e bremsstrahlung, stricter particle-id.

Misidentified hadronic background in e mode.

- Overall 0.2σ agreement with SM. Still stat limited.

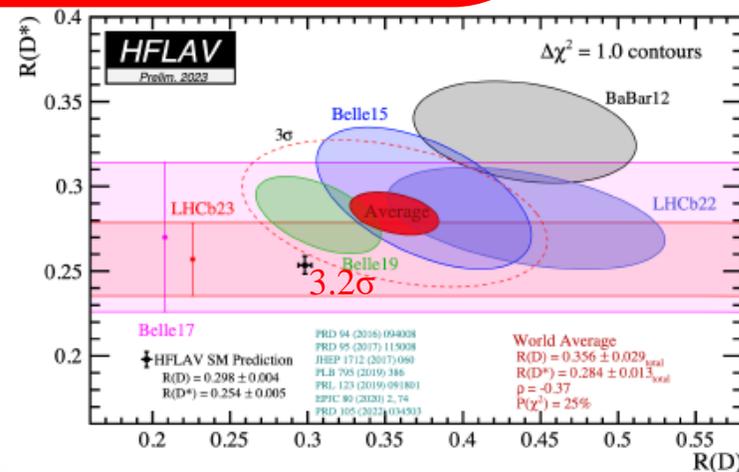

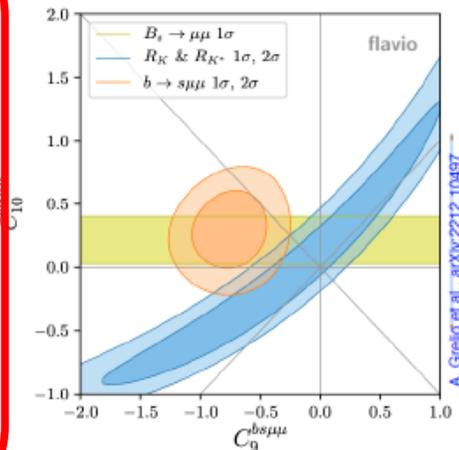

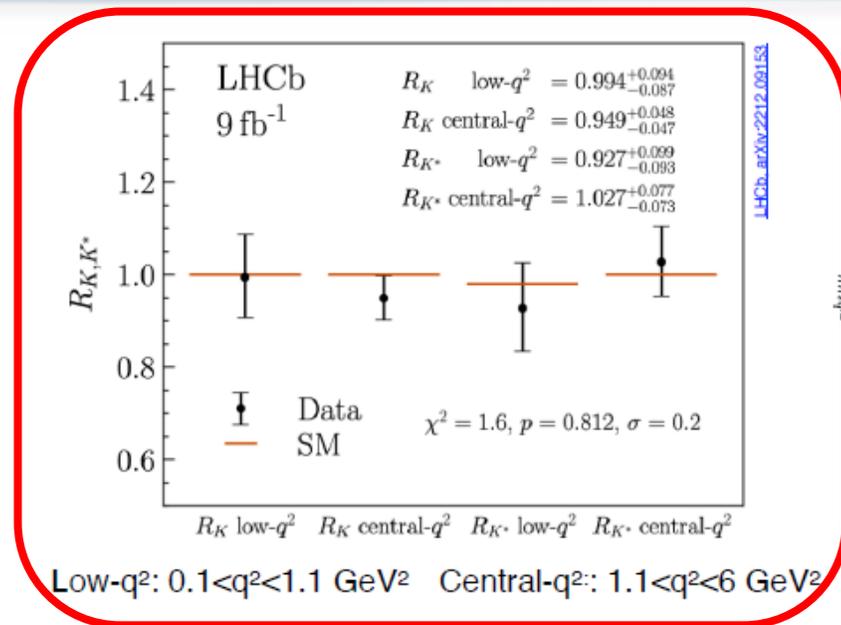

R_K, R_{K^*} Evaporated

New recent $b \rightarrow c l \nu$ LHCb measurements:

- $R(\Lambda_b)$ with $\Lambda_b \rightarrow \Lambda_c \tau \nu$. (LHCb Phys.Rev.Lett. 128 (2022))
- $R(D^{(*)})$ with $\tau \rightarrow \mu$ (LHCb arXiv:2302.02886) and hadronic τ (LHCb-PAPER-2022-052 in preparation).
- Move toward SM prediction. But Not Gone.

Discrepancies in other $b \rightarrow s l^+ l^-$ results remain:

- B.R., angular distributions.
- But less theoretically clean than ratios.

Isidori: "Not all is lost."

(Received 17 January 2023; accepted 10 March 2023; published 23 March 2023)

The LHCb Collaboration has recently released a new study of $B^+ \rightarrow K^+ \ell^+ \ell^-$ and $B \rightarrow K^{*0} \ell^+ \ell^-$ ($\ell = e, \mu$) decays, testing lepton universality with unprecedented accuracy using the whole Run 1 and 2 dataset. In addition, the CMS Collaboration has reported an improved analysis of the branching ratios $B_{(d,s)} \rightarrow \mu^+ \mu^-$. While these measurements offer, *per se*, a powerful probe of new physics, global analyses of $b \rightarrow s \ell^+ \ell^-$ transitions also rely on the **assumptions about nonperturbative contributions** to the decay matrix elements. In this work, we perform a **global Bayesian analysis** of new physics in (semi)leptonic rare B decays, paying attention to the **role of charming penguins** which are difficult to evaluate from first principles. We find data to be consistent with the Standard Model once **rescattering** from intermediate hadronic states is included. Consequently, we derive stringent bounds on lepton universality violation in $|\Delta B| = |\Delta S| = 1$ (semi)leptonic processes.

New Perspectives for Testing Electron-Muon Universality

Robert Fleischer ^{a,b}, Eleftheria Malami ^{a,c}, Anders Rehult ^a, and K. Keri Vos ^{a,d}

Abstract

Intriguing results for tests of the universality of electrons and muons through measurements of rates of $B \rightarrow K \ell^+ \ell^-$ and similar decays have been in the spotlight for years. The LHCb collaboration has recently reported new results which are in agreement with Lepton Flavour Universality, while the individual decay rates are found below their Standard Model predictions. In view of this new situation, we explore how much space is left for a violation of electron-muon universality. Considering new sources of CP violation and taking the new LHCb measurements into account, we show that significant differences between the short-distance coefficients for electronic and muonic final states are actually allowed by the current data. These patterns can be revealed through CP asymmetries in neutral and charged $B \rightarrow K \ell^+ \ell^-$ decays. We obtain correlations between these observables and map them to the short-distance coefficients. This results in regions in New Physics parameter space with large differences between CP asymmetries of the decays with final-state electrons and muons, thereby leaving a lot of room for possible surprises in the future high-precision era.

The Rumble in the Meson: a leptoquark versus a Z' to fit $b \rightarrow s\mu^+\mu^-$ anomalies including 2022 LHCb $R_{K^{(*)}}$ measurements

Ben Allanach^{a,b} and Joe Davighi^{c,1}

[Also Greljo et al., 2212.10497 \(12/20\)](#)

ABSTRACT: We juxtapose global fits of two bottom-up models (an S_3 scalar leptoquark model and a $B_3 - L_2$ Z' model) of $b \rightarrow s\mu^+\mu^-$ anomalies to flavour data in order to quantify statistical preference or lack thereof. The leptoquark model couples directly to left-handed di-muon pairs, whereas the Z' model couples to di-muon pairs with a vector-like coupling. $B_s - \bar{B}_s$ mixing is a focus because it is typically expected to disfavour Z' explanations. In two-parameter fits to 247 flavour observables, including $B_{s/d} \rightarrow \mu^+\mu^-$ branching ratios for which we provide an updated combination and LHCb $R_{K^{(*)}}$ measurements from December 2022, we show that each model provides a similar improvement in quality-of-fit of $\sqrt{\Delta\chi^2} = 3.6$ with respect to the Standard Model. The main effect of the $B_s - \bar{B}_s$ mixing constraint in the Z' model is to disfavour values of the $s_L - b_L$ mixing angle greater than about $5|V_{cb}|$.

(4) LUV gauge int.

But I'll follow a different path.

Non-universal gauge interactions addressing the inescapable link between Higgs and Flavour

Joe Davighi and Gino Isidori UV completion

Gino means it.

ABSTRACT: We systematically explore ultraviolet complete models where flavour hierarchies emerge, via approximate accidental symmetries, from an underlying flavour non-universal gauge structure. In order to avoid large quantum corrections to the Higgs mass, the first layer of non-universality, separating the third generation from the light ones, should appear at the TeV scale. A handful of models survive the combined criteria of naturalness in the Higgs sector, having a semi-simple embedding in the UV, and compatibility with experiments. They all feature quark-lepton unification in the third family and a non-universal electroweak sector. We study in more detail the interesting option of having colour and hypercharge non-universal at the TeV scale, while $SU(2)_L$ remains universal up to high scales: this gauge structure turns to be very efficient in secluding the Higgs from large quantum corrections and predicting flavour mixing consistent with data. In all cases, these models imply a rich TeV-scale phenomenology within the reach of near-future direct and indirect experimental searches.

(5) Everything Everywhere All at Once

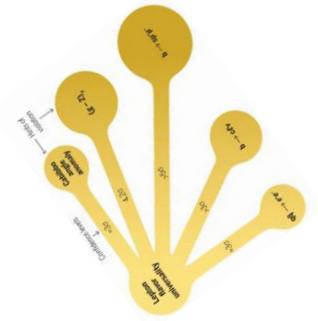

Anomalies in Particle Physics

Andreas Crivellin^{a,b}

Learn all the Anomalies here, if that's your creed.

I provide a (personal) review of the current hints for physics beyond the Standard Model, called “anomalies”, obtained both at the intensity frontier (flavour and electroweak precision observables) and in direct LHC searches. This includes the deviations from the Standard Model predictions in semi-leptonic B decays, the anomalous magnetic moment of the muon, the Cabibbo Angle Anomaly, the W mass as well as non-resonant di-lepton searches, the hints for new scalar particles around ≈ 95 GeV, ≈ 151 GeV, ≈ 670 GeV and the (di-)di-jet excess at ≈ 1 TeV (≈ 3.6 TeV). Possible explanations in terms of new particles are briefly summarized and discussed.

Search for Flavor-Changing Neutral Current Interactions of the Top Quark and Higgs Boson in Final States with Two Photons in Proton-Proton Collisions at $\sqrt{s} = 13$ TeV

A. Tumasyan *et al.**
(CMS Collaboration)

Ⓞ (Received 3 November 2021; accepted 13 June 2022; published 13 July 2022)

Proton-proton interactions resulting in final states with two photons are studied in a search for the signature of flavor-changing neutral current interactions of top quarks (t) and Higgs bosons (H). The analysis is based on data collected at a center-of-mass energy of 13 TeV with the CMS detector at the LHC, corresponding to an integrated luminosity of 137 fb^{-1} . No significant excess above the background prediction is observed. Upper limits on the branching fractions (\mathcal{B}) of the top quark decaying to a Higgs boson and an up (u) or charm (c) quark are derived through a binned fit to the diphoton invariant mass spectrum. The observed (expected) 95% confidence level upper limits are found to be 0.019% (0.031%) for $\mathcal{B}(t \rightarrow Hu)$ and 0.073% (0.051%) for $\mathcal{B}(t \rightarrow Hc)$. These are the strictest upper limits yet determined.

ABSTRACT

We study electroweak baryogenesis driven by the top quark in a general two Higgs doublet model flavor-changing Yukawa couplings, keeping the Higgs potential CP invariant. With Higgs sector coupling and the additional top Yukawa coupling ρ_{tt} all of $\mathcal{O}(1)$, one naturally has sizable CP violation that the cosmic baryon asymmetry. Even if ρ_{tt} vanishes, the favor-changing coupling ρ_{tc} can still lead successful baryogenesis. Phenomenological consequences such as $t \rightarrow ch$, $\tau \rightarrow \mu \nu$ electron electric dipole moment, $h \rightarrow \gamma \gamma$, and hhh coupling are discussed.
