

A search for semi-visible jets in non-resonant production mode in ATLAS

Deepak Kar

Based on: [ATLAS-CONF-2022-038](#)

at LHC DM WG, 12/01/2023

The big picture!

We have not found any concrete signs of new physics ... yet!

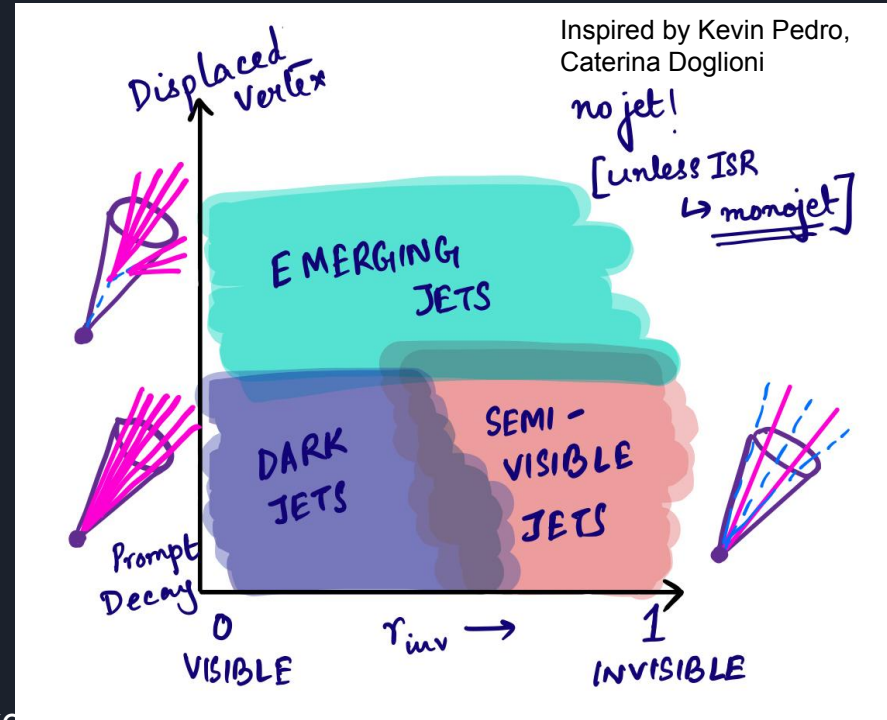

Looking at unusual topologies and hidden corners of the phase space

→ signature based searches, using benchmark models.

Dark hadrons decaying PROMPTLY in a QCD-like fashion, fully (dark jets)

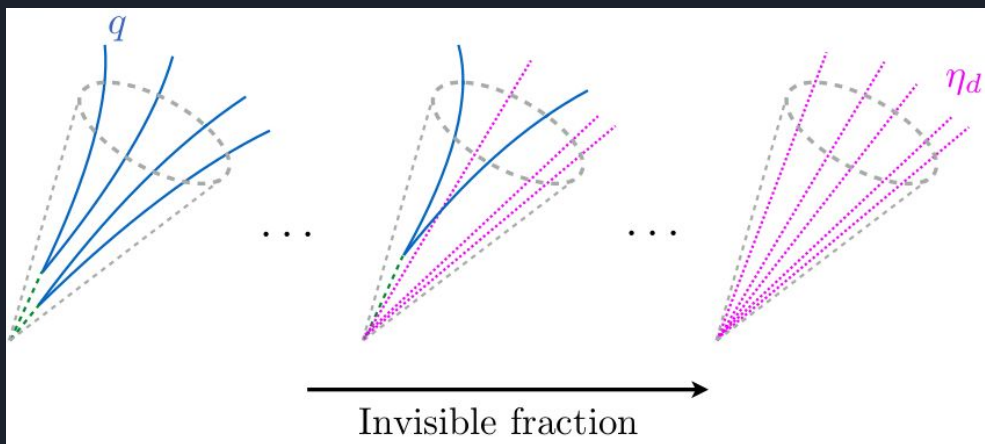

or partially back to visible sector (semi-visible jets)

Dark hadrons undergoing DISPLACED decays in a QCD-like fashion (emerging jets)

Showering using Pythia hidden valley module: at best a guesstimate!

Semi-visible jet production

Model Parameters:

1. M_ϕ = Mass of Scalar Bi - fundamental
2. r_{inv} = no. of stable invisible hadrons/ no. of hadrons
3. M_d = Mass of dark hadrons
4. $\lambda = q - \phi - q_d$ coupling strength

Quantum
fluctuations, and
boost by extra
jets, creates
MET

This is how a
signal event
should look
like!

Analysis preselections

Signal samples: Madgraph + Pythia8 with $R_{\text{inv}} = 0.2, 0.4, 0.6, 0.8$ and $M_d = 10 \text{ GeV}, M_\phi = 1 - 5 \text{ TeV}$

Background samples: W/Z+jets, ttbar, singletop, multi-jet, diboson

1. Looking at events with MET trigger, $\text{MET} > 200 \text{ GeV}$
2. At least 2 jets ($R=0.4$) with leading jet $p_T > 250 \text{ GeV}$, other jet $p_T > 30 \text{ GeV}$ and $|\eta| < 2.8$
3. No electrons / muons ($p_T > 7 \text{ GeV}$)
4. Dead-tile correction, LAr, SCT error veto, NCB treatment for data
5. $\Delta\Phi(\text{closest jet, MET}) < 2.0$
6. B-tagged jets < 2
7. Tau jets ($p_T > 20 \text{ GeV}$) < 1

MET > 600 GeV and $H_T > 600 \text{ GeV}$ after the nominal selection defined as signal region (SR).

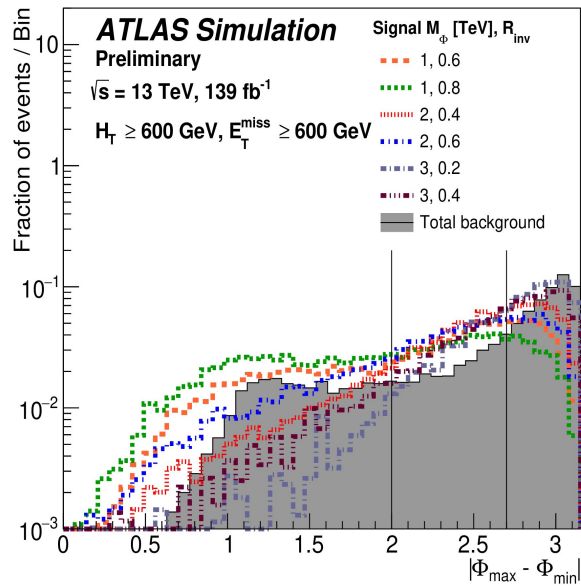

The corresponding 1L, 1L1B and 2L control regions (CR) defined using leptonic selections (and leptons added back to MET) with same MET and H_T requirements as in SR.

Key Observables

1. the p_T balance between the closest jet (j_1) and farthest jet (j_2) from E_T^{miss} direction, termed as p_T^{bal} :

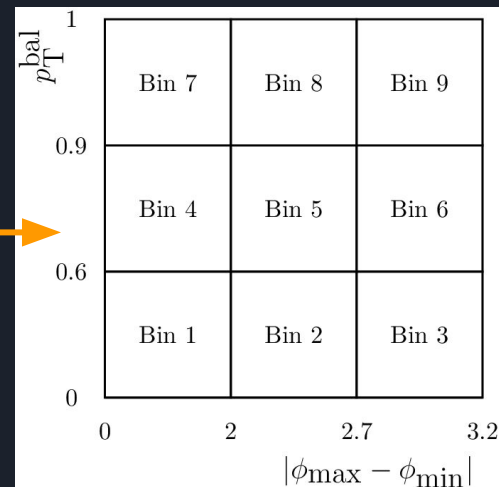

$$p_T^{\text{bal}} = \frac{|\vec{p}_T(j_1) + \vec{p}_T(j_2)|}{|\vec{p}_T(j_1)| + |\vec{p}_T(j_2)|}$$

2. the difference in the azimuthal angle between j_1 and j_2 as defined above, termed $|\phi_{\text{max}} - \phi_{\text{min}}|$:

Yields in these nine bins ((3 max-minphi bins)x(3 p_T balance bins)) are treated as the observables in different regions.

Contribution of different backgrounds is different for each of the bins, so the signal-depleted but specific background-enriched bins in the SR itself are used to estimate the background.

Fit Strategy & 9-bin histograms - CR

CR 1L: used to control W+jets / single top background contributions

CR 1L1B: used to control $t\bar{t}$ / single top background contributions

CR 2L: used to control Z+jets background contributions

Simultaneous maximum likelihood function fit performed using the product of all relevant Gaussian and Poisson PDFs and 9-bin yields, using MC templates, with dedicated theoretical and experimental systematic uncertainties for 0L SR, 1L CR, 1L1B CR, 2L CR (details in backup)

9-bin & Kinematic distributions - SR

We haven't found new physics :- (Excellent agreement between data and estimated background...

The largest post-fit effects: signal modelling uncertainties $\sim 8\%$, Z+jets modelling uncertainties $\sim 7\%$, top process modelling uncertainties $\sim 4\%$. The rest of the contributions are less than 2%.

Systematic Uncertainties

- Largest contribution from theoretical components (~25% on signal cross-sections mostly from scale variations).
 - Apart from usual scale and PDF variations, also included $t\bar{t}$ and single top I/FSR variation, ME and PS variation by using alternate generators, DR/DS subtraction scheme difference for tW .
 - W +jets split into heavy and light flavour, and an extra 30% normalisation uncertainty was used for heavy flavour, since Sherpa 2.2 has been found to underestimate V +heavy-flavour by about a factor of 1.3
- Standard experimental uncertainties: JES/JER, MET soft term, luminosity, PU reweighting, flavour tagging, reconstruction/identification/isolation/trigger efficiencies on muon and tau leptons.

95% CL Limits on mediator mass

Assuming unity coupling between $q - \phi - q_d$, can exclude mediator masses upto 2.7 TeV, subject to values of R_{inv}

Search for non-resonant production of semi-visible jets using Run 2 data in ATLAS

ATLAS-CONF-2022-038 [CDS link](#)

Summary

First result on this production mode, and more importantly first look at this challenging topology.

The ATLAS paper is in preparation, with minor fix of HV parameters, results do not change much.

Many other striking signatures exists, including SVJ with heavy flavour (preliminary study by SS and DK on arXiv, work in progress).

BACKUP

HV Parameters (why and what)

Parameter	value
HiddenValley:N _{gauge}	2
HiddenValley:FSR	on
HiddenValley:spinFv	0
HiddenValley:fragment	on
HiddenValley:pTminFSR	1.1
HiddenValley:probVector	0.75
HiddenValley:alphaOrder	1
HiddenValley:Lambda	0.1
HiddenValley:alphaFSR	1.0

All parameters set as per theory paper

Running HV alpha selected, after discussions with theorists in different platforms (Snowmass, LHC DMWG). Advised to be the safest choice for first analysis.

Semi-visible jets in ATLAS - Analysis Samples

Signal: Madgraph + Pythia8 with $R_{\text{inv}} = 0.2, 0.4, 0.6, 0.8$ and $M_d = 10 \text{ GeV}$, $M_\phi = 1 - 5 \text{ TeV}$ (in 500 GeV intervals)

Background samples:

Statistical analysis

- To determine individual $N_i \rightarrow$ simultaneous binned maximum likelihood function fit is performed using product of all PDF_{*i*} and nine bin yields, using the MC templates
- The fit maximises the likelihood function constructed from the product of all relevant Poisson and Gaussian pdfs. The scale factors for the individual backgrounds, k^{SF} are determined from the fit:

$$\mathcal{L}(\mu, \theta) = \prod_{j \in 36 \text{ bins}} \text{Poisson}(N_j^{\text{obs}} | \mu N_j^{\text{sig}}(\theta)) + \sum_{i \in \text{bg}} k_i^{\text{SF}} \times N_{i,j}^{\text{bg}}(\theta) \times f^{\text{constr}}(\theta)$$

Here, N_j^{obs} is the observed total yield in the bin j , signal strength is μ , systematic uncertainties in the fit are denoted by nuisance parameters θ , $N_j^{\text{bg}}(\theta)$ is the combined background yield in bin j

The term $f_{\text{constr}}(\theta)$ represents the product of the gaussian constraints applied to each of the nuisance parameters,

$$f_{\text{constr}}(\theta) = \prod_{k=1}^M G(\theta_k^0 - \theta_k)$$

Kinematic distributions - SR

We haven't found new physics :-)

Excellent agreement between data and estimated background...
