

# Laser-cooling cadmium with only UVA Triplet Excitations & Cd Isotope Shifts

- Cadmium optical lattice clocks
  - Small BBR sensitivity
  - Narrow-line cooling & magic wavelength
- Laser-cooling without UVC – UVA & blue triplet excitations
  - Only small MOT gradients are required
  - Low temperatures & 100% transfer to narrow-line MOT
- Cd fermions,  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ 
  - Spin  $\frac{1}{2}$  & negative nuclear magnetic moments
  - No additional repumping required
- Isotope shifts & King plots for beyond SM Physics
  - 6 stable spin 0 isotopes,  $^{106}\text{Cd}$  to  $^{116}\text{Cd}$
- UVA SFG lasers and FPGA control system
- Absolute frequency measurement of  $361\text{ nm } ^3\text{P}_2 \rightarrow ^3\text{D}_3$

# Atomic Clock Candidates

- Dominant lattice clock uncertainties have been AC Stark Shifts: from blackbody radiation and higher order shifts from the lattice light.
- Hg, Cd, Zn & Mg have small sensitivities to BBR.

Clock	$\pm 0.1K$ BBR ( $10^{-18}$ )	$^3P_1 \Gamma$ (kHz)	$^3P_1 \lambda$ (nm)	Magic $\lambda_m$ (nm)	# of $l=1/2$ Fermions	$l$ of Fermions	1 mTorr pressure ( $^{\circ}C$ )
Cs	23						
Rb	16						
Sr	7.3	7	689	813		9/2	465
Yb	3.3	182	556	760	1	1/2, 5/2	520
Ca	3.3	0.4	657	680			405
Mg	0.53	0.036	457	469		5/2	370
Cd	0.38	67	326	420	2	1/2, 1/2	215
Hg	0.24	1,300	254	363	1	1/2, 3/2	<22
Al <sup>+</sup>	0.005						

- Wavelengths are easier for Cd than Hg?
  - Cd 229 nm & Hg 1.3 MHz wide  $^1S_0 \rightarrow ^3P_1$  254 nm are UV-C.
  - Trap Cd with only UVA.

NIST Yb Shift $10^{-18} \nu_{clock}$	Yb-1 shift	Yb-1 uncertainty	Yb-2 shift	Yb-2 uncertainty

<sup>1</sup>Based upon <sup>12</sup>C. ( ) indicates the mass number of the longest-lived isotope.

For the most precise values and uncertainties visit [ciaaw.org](http://ciaaw.org) and [pml.nist.gov/data](http://pml.nist.gov/data).  
NIST SP 966 (July 2019)

- Hg, Cd, & Mg have small sensitivities to BBR shifts.
  - 229 nm is UV-C.
  - $\sim 10^6$  atoms
- Wavelengths and Doppler and sideband cooling are easier for Cd than Hg.
  - $1S_0 \rightarrow 3P_1$  Doppler cooling to 5.6  $\mu\text{K}$ .
  - Magic wavelength is 419.88 nm.
  - MOT gradients: 170G/cm & 1 G/cm.

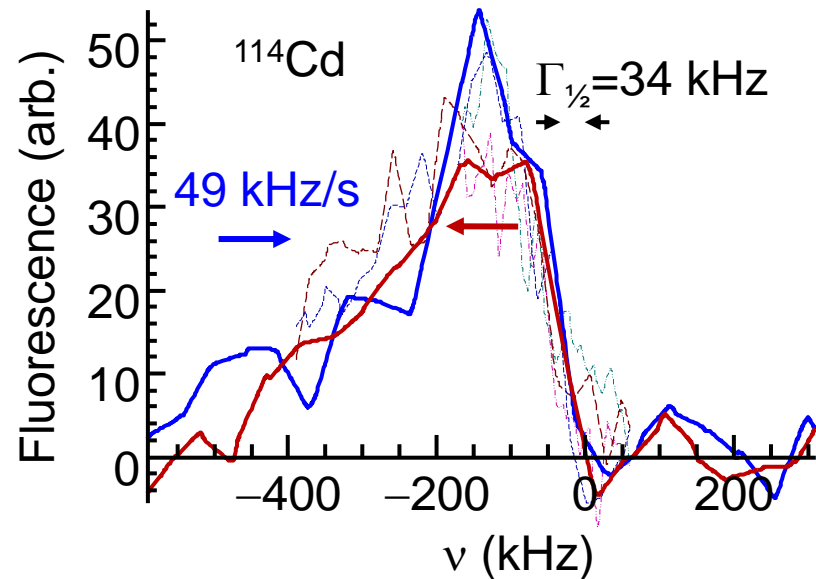

Transportable Cd clock:

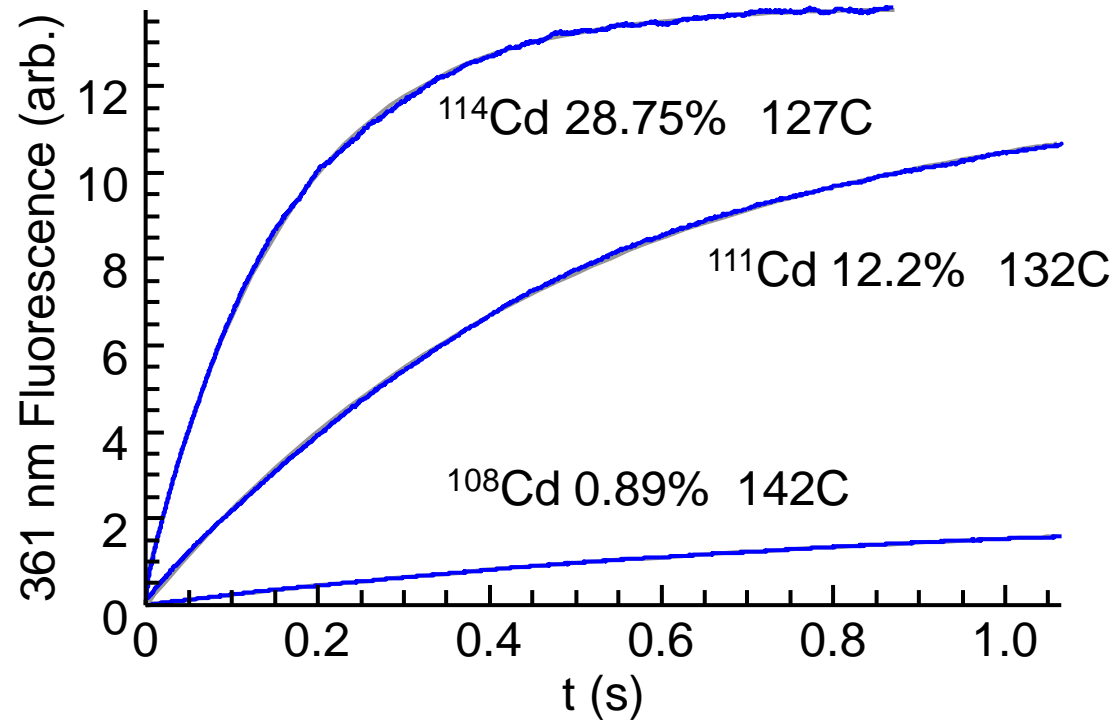

# PSU Laser Cooling and Trapping of Cd

- Try to use only UVA - avoid 229 nm light.
- First, can only 326 nm light capture atoms with a 67 kHz linewidth transition from a room temperature source?
  - 6 Bosons: Trap & cool 4 of 6 bosonic ( $^{110}\text{Cd}$ ,  $^{112}\text{Cd}$ ,  $^{114}\text{Cd}$  &  $^{116}\text{Cd}$ ) and both fermionic isotopes ( $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ ).
  - $^{106}\text{Cd}$  &  $^{108}\text{Cd}$  have ~1% abundance
- 8.6 MHz FM of narrow 326 nm laser to broaden capture velocity.
  - 50 to 150 mW of 326 nm light
  - MOT gradient: 0.5 G/cm

# Enhanced Loading with a Cd Metastable MOT

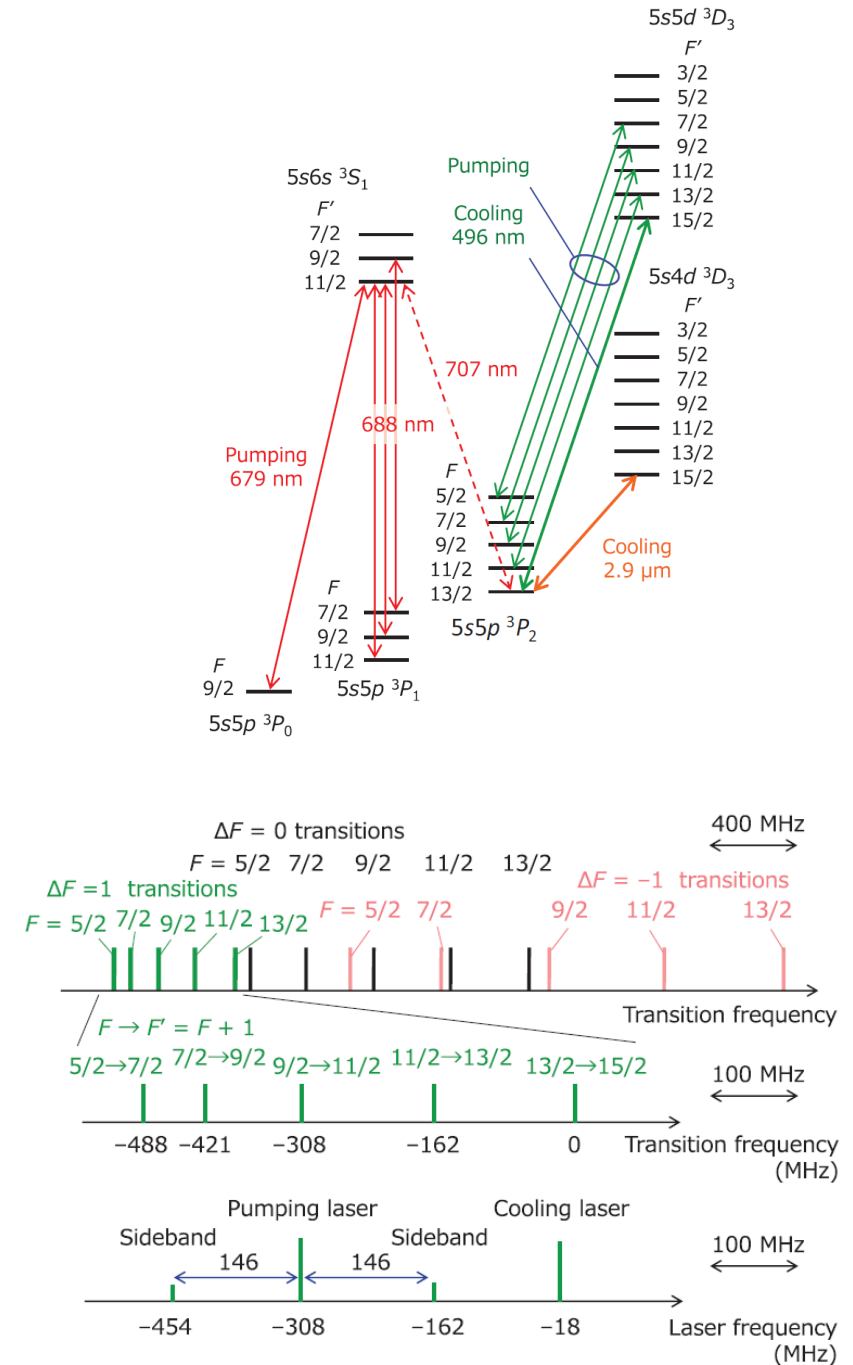

- Use only UVA & blue triplet excitations - no 229 nm light.
- 361 nm meta-stable MOT loading:
  - $\sim 10^{10}$  atoms, 10 $\times$  RIKEN 229 nm MOT
  - 361 nm also gives high S/N detection
- Trap all 6 Bosons:  $^{106}\text{Cd}$ ,  $^{108}\text{Cd}$ ,  $^{110}\text{Cd}$ ,  $^{112}\text{Cd}$ ,  $^{114}\text{Cd}$  &  $^{116}\text{Cd}$ 
  - MOT gradient: 5.7 G/cm (170 to 400 G/cm for 229 nm singlet MOT).

- 2 Fermion spin  $\frac{1}{2}$  isotopes:  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ 
  - Spin  $\frac{1}{2}$  nuclei (& negative magnetic moments)

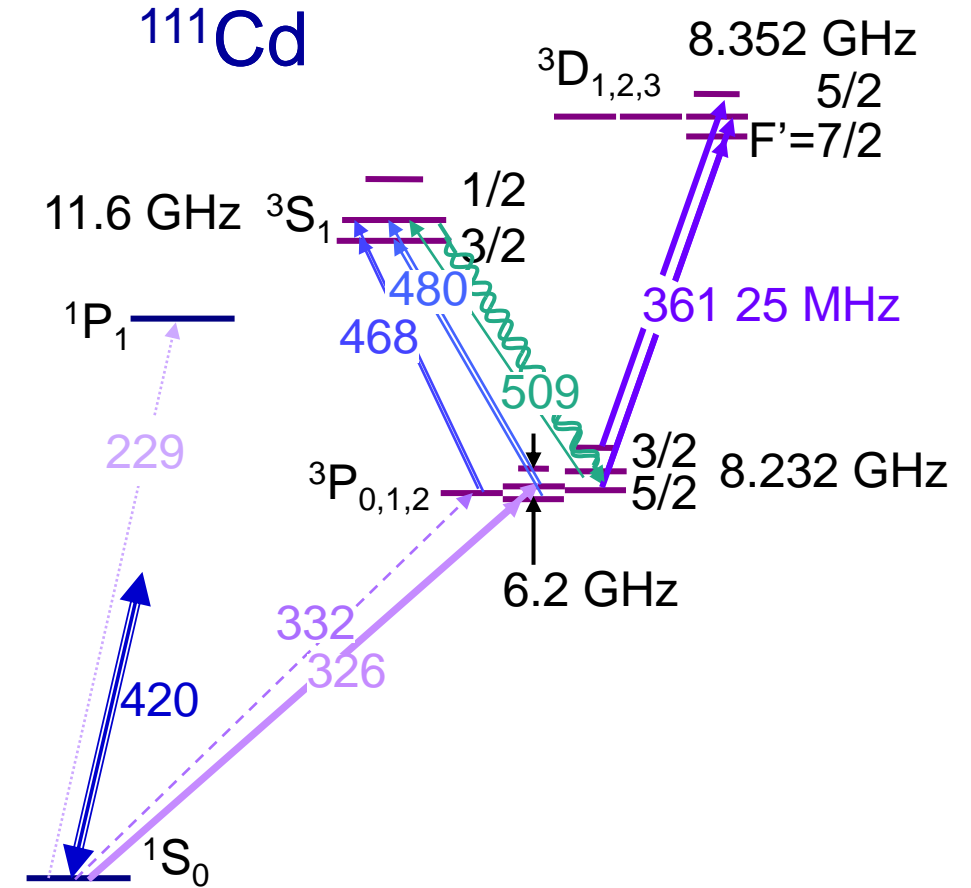

# Metastable MOT of Sr Fermions

- Sr has spin 9/2 nucleus -  $^3D_3$  splits into 7 hyperfine levels

# Metastable Trapping of Cd Fermions

- 2 Fermion isotopes,  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ , both with:
  - spin  $\frac{1}{2}$  nuclei  $\rightarrow$  only 2 hyperfine sub-levels
  - negative nuclear magnetic moments  $\rightarrow$  inverted hfs.
- $\rightarrow$  No additional lasers are needed to laser cool Cd fermions.

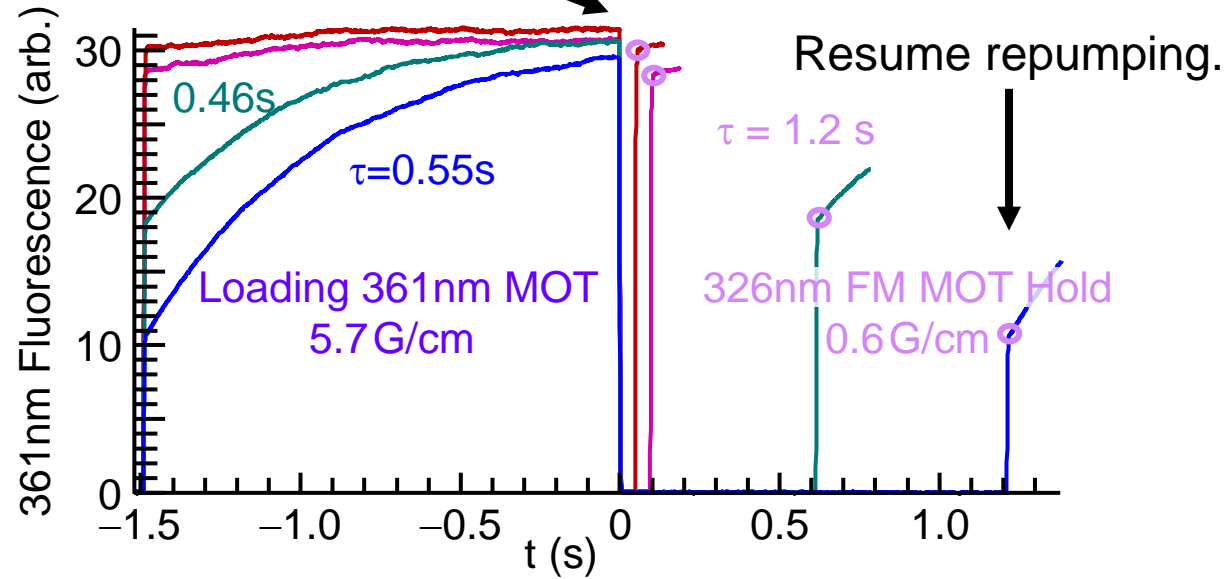

- Large loading rates of all 8 stable bosonic & fermionic isotopes.

# Transfer from Metastable MOT to Narrow Line MOT

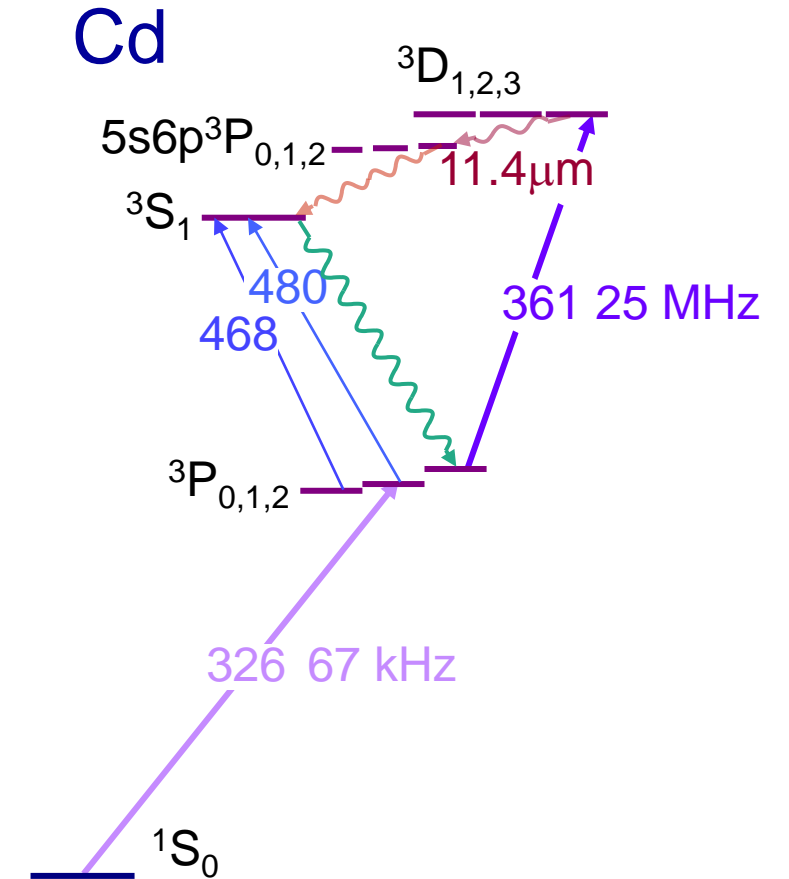

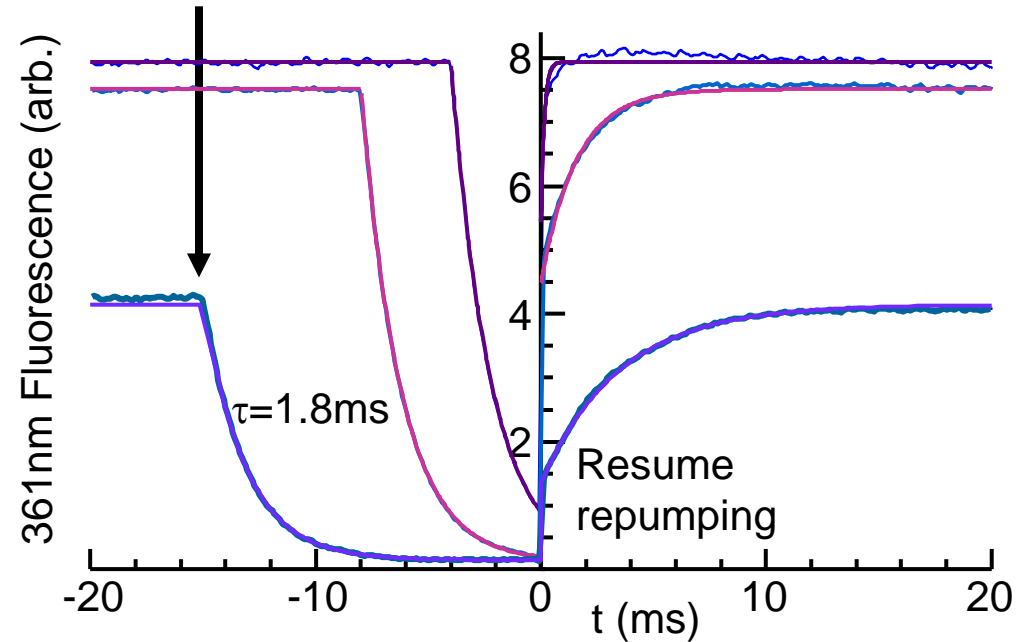

- Inhibit 480 nm  $^3P_1$  repumping to transfer  $^{114}\text{Cd}$  to 326 nm FM MOT.

- All atoms are transferred from 361nm MOT to 326nm FM MOT.
- 326nm FM MOT holds atoms for a long time.
- Light assisted, fine structure changing, or energy pooling  $^3P_2$  collisions?

# Metastable $^3P_2$ and $^3P_0$ collisions

- Inhibit 468 nm  $^3P_0$  repumping to transfer  $^{114}\text{Cd}$  to (untrapped)  $^3P_0$  state.

- 361nm MOT continues to more slowly accumulate atoms, loading them into  $^3P_0$ .
- With atoms in  $^3P_0$ , more atoms are trapped than when all atoms are in  $^3P_2$ .
- More investigation needed to confirm  $^3P_2$  fine-structure changing collisions are the dominant 361nm MOT loss mechanism.

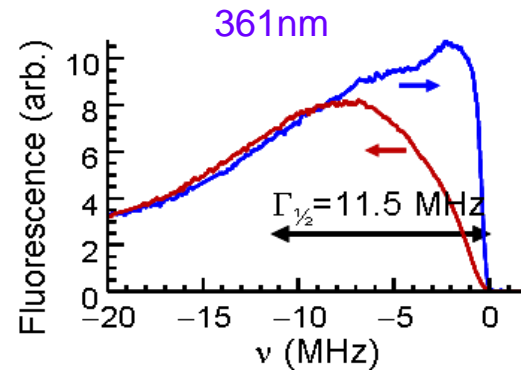

# Isotope Shifts – a Probe of Beyond Standard Model Physics

- “Normal Mass Shift” - the frequencies of deuterium transitions are higher than hydrogen’s:

$$E_n = -\frac{Ry}{n^2} \frac{1}{1 + \frac{m_e}{m_{nuc}}}$$

$$\delta\nu_i^{A,A'} = F_i \delta\lambda^{A,A'} + K_i \mu^{A,A'}$$

- There is also the “Specific Mass Shift” – electrons of multi-electron atoms, including relativistic shifts.
- The “Field Shift” is the overlap of electrons with the nuclear charge distribution. It can be large in heavy atoms.
- King Plots: ( $l=0$ ) isotope shifts of frequencies of 2 transitions, divided by  $\mu$ , the inverse nuclear mass difference.

Reference cavity:  
905.03 MHz FSR,  
140.84 MHz & 201.04 MHz  
transverse mode splittings.

- 326 nm measurements clarified ISS &  $4\sigma$  nuclear charge radius discrepancy from 1959:  $F_{326} = -4354(62)$  MHz/fm<sup>2</sup>, previously  $-6200(500)$  MHz/fm<sup>2</sup>.
- First measurements of 480nm & 361nm ISS’s.

Isotope	326nm (MHz)	Cd <sup>+</sup> 214 nm	480nm (MHz)	361m (MHz)
106	1913.0	2991	-798.5	-607.6
108	1402.4	2194	-586.7	-447.4
110	914.7	1432	-383.4	-293.9
112	429.9	675	-183.1	-142.2
114	0	0	0	0
116	-321.5	-527	152.7	122.0

Kelly & Tomchuk, Proc. Phys. Soc. '59

# Yb Isotope Shifts

- Frequency measurements of 5 Yb<sup>+</sup> & Yb isotopes give a pattern of King Plot non-linearities.
  - An important check of SM & for searches for BSM physics.
- 2 possible nonlinearities for 5 measurements: + -- + and - + - +.
  - Nuclear deformations may explain most of the deviations.
- Search for intermediate-mass bosonic candidate for Dark Matter.

# Cd Isotope Shifts and Probing Beyond Standard Model Physics

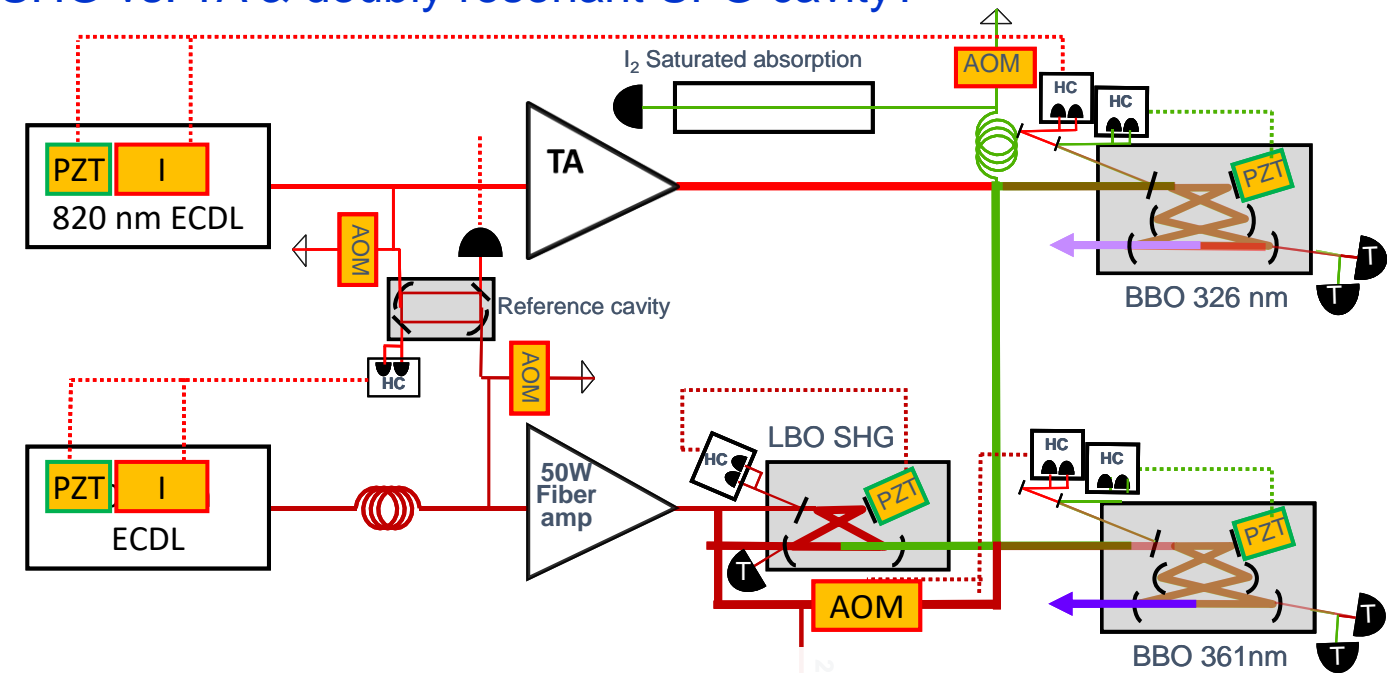

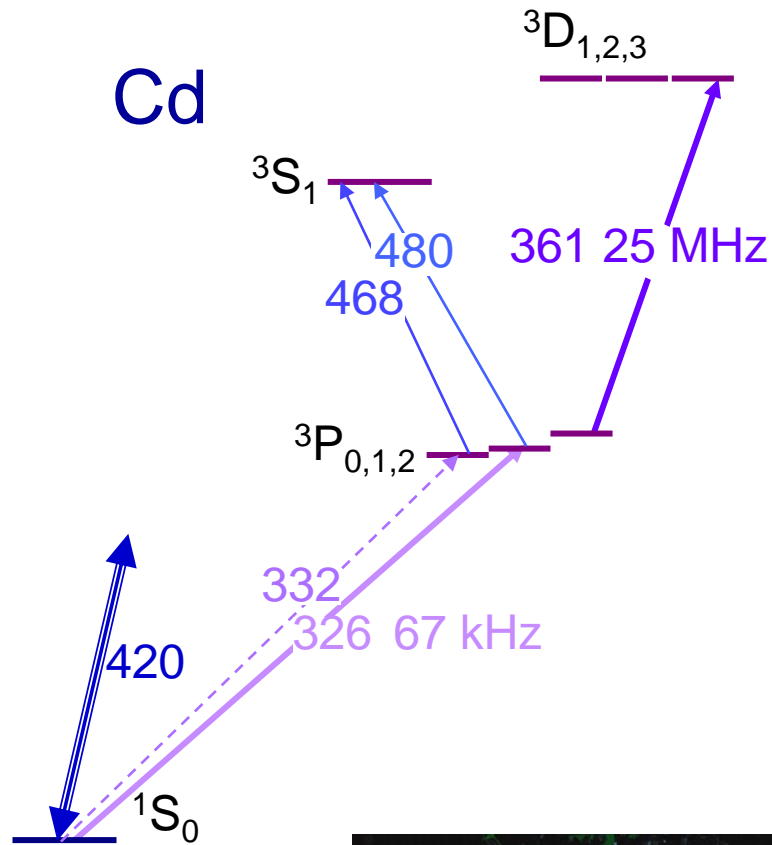

- A King Plot nonlinearity from at least 4  $I=0$  isotopes.
  - More isotopes improves the check of the ISS pattern.
- Cd has 6  $I=0$  isotopes, moderately heavy, with smaller nuclear deformations than Yb.
  - $\text{Cd}^{48}$  is close to the  $Z=50$  proton shell gap.
- The sensitivity to new physics should be similar to the difference of the Field Shifts of two transitions.
- Two possibilities:
  - Precise measurements of 2 narrow transitions.
  - One narrow transition & one between higher states with a very different Field Shifts.
- ISs & precise structure calculations determine  $F_{D2}$  &  $K_{D2}$  for  $\text{Cd}^+$  (&D1).  $F_i$  &  $K_i$  for other transitions can then be bootstrapped from King Plots.
  - 60× more precise differences of charge radii than  $e^-$  & muonic x-ray scattering.

# (Too?) Elegant Scheme to Generate Cd Wavelengths

- 50 W Fiber Amplifier
- Single reference cavity for all lasers: 905.03 MHz FSR, 140.84 MHz & 201.04 MHz transverse mode splittings.
- Auto-locks with a single FPGA
- Switch to SHG vs. TA & doubly resonant SFG cavity?

# 361 nm $^3P_2 - ^3D_3$ Transition Frequency Measurement

- From  $I_2$  coincidence we get:  $\nu_{^{114}\text{Cd}} = 3/2 \nu_{\text{R83 28-0 a7}} + 261(3)$  MHz.
- The previous measurement was Adam & Burns '56.
  - The paper had a typographical error of  $0.010 \text{ cm}^{-1}$  (300 MHz). (Alexander Kramida, NIST, database to be corrected)
- Many  $I_2$  lines have been measured with frequency combs. A molecular model with hyperfine interactions gives nearby lines to 10 MHz (Tiemann, Hannover).

$\nu_{\text{R83 28-0 a7}} = 553,397,541(10)$  MHz  
 $\rightarrow$  Natural Cd  $^3D_3$ :  $59515.990 \text{ cm}^{-1}$

– Previous uncertainty of 300 MHz  $\rightarrow$  15 MHz from  $I_2$ .

# Summary

- Cadmium for optical lattice clocks
  - Small BBR sensitivity
  - Narrow-line cooling & magic wavelength
- MOT using only 50 mW of 326 nm light exciting the 67 kHz wide  $^1S_0 \rightarrow ^3P_1$  transition
- Large MOT without UVC light – UVA & blue triplet excitations
  - Only small MOT gradients are required, < 6 G/cm
  - Low temperatures & 100% transfer to narrow-line MOT
- Cd fermions,  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ 
  - Spin  $\frac{1}{2}$  & negative nuclear magnetic moments
  - No additional repumping required
- Isotope shifts & King plots for beyond SM Physics
  - 6 stable spin 0 isotopes,  $^{106}\text{Cd}$  to  $^{116}\text{Cd}$
- UVA SFG lasers with an auto-locking FPGA control system
- Absolute frequency measurement of 361 nm  $^3P_2 \rightarrow ^3D_3$ 
  - $f_{114\text{Cd}} = 3/2 \nu_{\text{R83 28-0 a7}} + 261(3) \text{ MHz}$

# Many Channel FPGA System with Auto-Lock

- Auto-lock entire system with a single FPGA module
- 9 fast servos with MHz bandwidth, 3 AWG's, 8 slow (temperature) servos, DSP ...
- Touch-screen control:

- Simplified IIR PID's:

$$y_0 = a_1 y_1 + b_0 x_0 + b_1 x_1$$

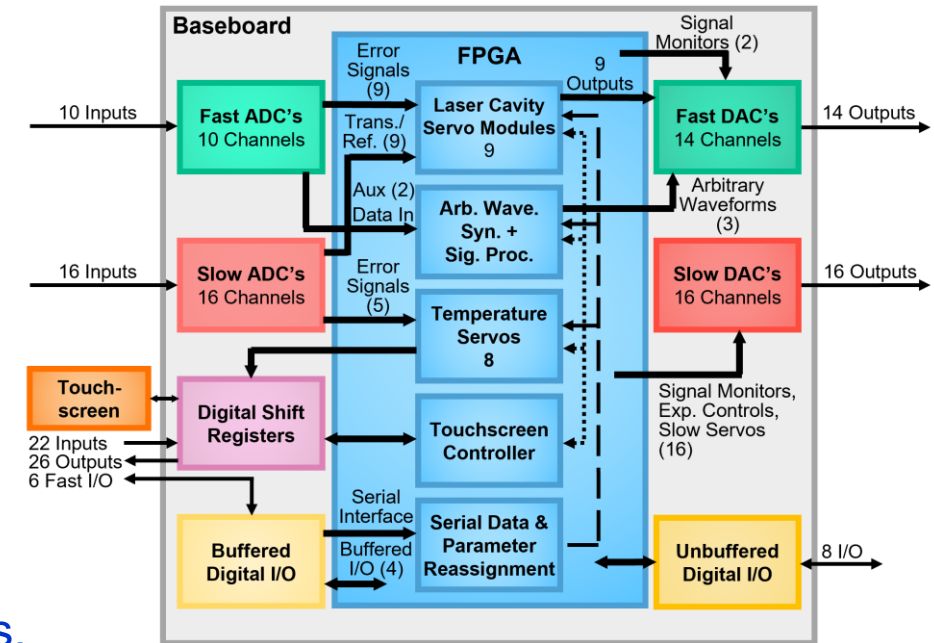

- Typical servo gain margins are  $\times 2$  or  $2^{1/2}$
- Many servo's have gain and frequency resolution of 1,2,5,10 ...
- Other FPGA servos use large multipliers – timing can be challenging at  $\geq 100$  MS/s.
- Multiplications by  $2^n$  are fast and efficient.

$$a_1 = 1 - \tilde{\omega}_H \quad b_0 = b_1 = \tilde{G}/2$$

$$y_0 = y_1 - \tilde{\omega}_H y_1 + \frac{\tilde{G}}{2}(x_0 + x_1)$$

- We get 25% gain and frequency resolution with one optional addition: 0.875, 1, 1.25, 1.5, 1.75, 2...

$$\tilde{G}, \tilde{\omega}_H \dots = 2^n \left( 1 + \left\{ -\frac{1}{8}, 0, \frac{1}{4}, \frac{1}{2} \right\} \right)$$

# FOCOS – Fundamental Physics with an Optical Clock Orbiting in Space

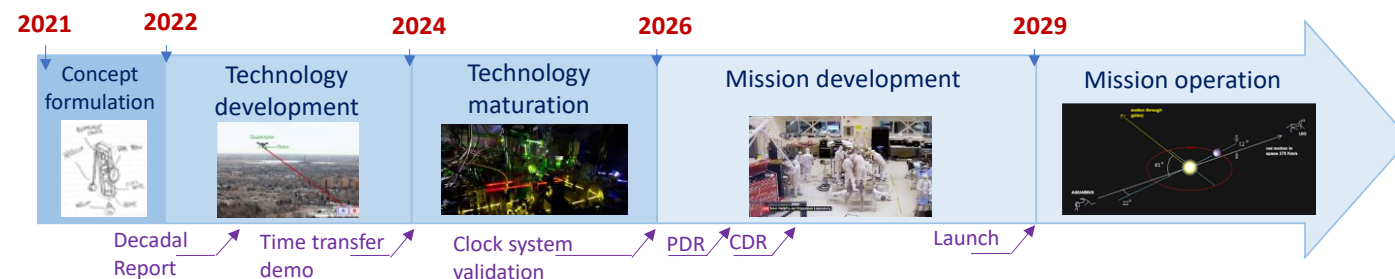

- Yb lattice clock:  
 $1 \times 10^{-18}$  accuracy &  $1 \times 10^{-16} \tau^{-1/2}$  stability.
- Test redshift at  $1 \times 10^{-9}$  (30,000  $\times$  improvement)
- Test Local Lorentz Invariance
- World-wide network of atomic clocks
- Searches for Dark Matter on Earth and in space.
- Precision geodesic referencing at the mm-level
- Redefinition of the SI second & space-time reference.

- C. Oates, NIST
- K. Gibble, PSU
- L. Hollberg, Stanford
- N. Newbury, NIST
- N. Yu, CalTech-JPL
- A. Derevianko, U. Nev, Reno
- M. Safronova, U. Del.
- L. Sinclair, NIST

An 8 hr. orbit inclination of  $9.3^\circ$  gives perigee and apogee maximum elevations of  $30.4^\circ$  at  $40^\circ$  N for a 5,000 km perigee altitude.

Quantum Science and Technology 7 044002 '22

# ACES: Atomic Clock Ensemble in Space

Laser-cooled (microwave) Cs clock on the International Space Station.

- $10^{-16}$  accuracy goal
- Time Transfer
- Gravitational Redshift
- Time Dilation
- Time variation of the fine structure constant
- Geodesy
- Launch in 2025.

PHARAO: Projet d'Horloge Atomique par Refroidissement d'Atomes en Orbit

PHARAO ( $10^{-16}$ )	Shift	Uncertainty
Quadratic Zeeman	900	0.1
Blackbody radiation	-172	0.7
Ultracold collisions & cavity phase		$0.68 \text{ yr}^{-1/2}$
Microwave Lensing	1.15	0.4
<b>Total</b>		<b>1.1</b>

# (1<sup>st</sup> order) Doppler Shift - “Distributed Cavity Phase Shift”

Atom motion plus a spatial phase variation of an electromagnetic field.

Standing wave + **traveling wave** → spatially varying phase

$$\delta\nu = \frac{\Phi_{up} - \Phi_{down}}{\pi} \Delta\nu$$

Known since 1970’s – surprisingly, no prior calculations agreed with measurements.

Large finite-element E&M calculations agree with no free parameters.

2D FEM for fountains – Fourier azimuthal decomposition in  $\cos(m\phi)$

3D FEM for PHARAO/ACES (1 TB RAM)

New fountain cavity design reduces Doppler uncertainty from  $\pm 3 \times 10^{-16}$  to  $\pm 0.5 \times 10^{-16}$ .

# Microwave Photon Recoil?

Infinite plane wave

$$\frac{hc}{\lambda} = \hbar k$$

$$mv_x = \hbar k = \frac{hc}{\lambda}$$

$$v_x \approx 0.1 \mu m / s$$

Recoil Frequency Shift:  
Conserve E & p.

$$\frac{\delta\nu}{\nu} = \frac{\hbar^2 k^2}{2m\hbar\omega} = \frac{\hbar\omega}{2mc^2}$$

$$= \pm 1.5 \times 10^{-16}$$

# Is an atom's recoil equal to $\hbar k$ ?

Finite beam:

Maxwell: 
$$(\nabla^2 + k^2) E = 0$$

so 
$$k_x^2 + k_y^2 + k_z^2 = k^2 \quad \& \quad k_x < k$$

$$k_{y,z} \approx \frac{2}{w_0 = 2mm} \Rightarrow \delta k_x = -8 \text{ ppb}$$

Three appealing choices:

1. The photon momentum comes in discrete units of  $k$ , in the  $x$  direction.
2. The atom has a recoil of  $k_x$  in the  $x$  direction;  $v_y$  &  $v_z$  are unchanged.
3. The atom has a recoil of  $k_x$  in the  $x$  direction, and also  $\pm k_y$  &  $\pm k_z$ .

# Transverse (Microwave) Photon Recoils?

There is no grating in the z direction.

→ No recoil in z direction.

“Microwave” Stern-Gerlach regime

Same problem for microwave clocks: The dipole force of the microwave field acts as a lens on the atomic wavefunctions.

Shift:  $\approx \pm 4\text{nm}$

$\Delta\text{width: } \approx \pm 2\text{nm}$

$$\delta P = \left[ \left| \langle 2 | \Psi(t_2) \rangle \right|^2 - \left| \langle 1 | \Psi(t_2) \rangle \right|^2 \right] \sin \left[ \frac{\pi}{2} \cos(k_x x) \right]$$

$$\delta\nu \neq \frac{\hbar k^2}{4\pi m}$$

$$\frac{\delta\nu}{\nu} \neq 1.5 \times 10^{-16}$$

$$\delta\nu = \frac{\pi}{2} \Delta\nu_R \frac{w_1}{w_2}$$

$$\frac{\delta\nu}{\nu} \approx 7 \times 10^{-17}$$

The majority of primary clocks correct the not-yet-observed bias that we calculate.

# Microwave Lensing & Photon Recoil Shifts

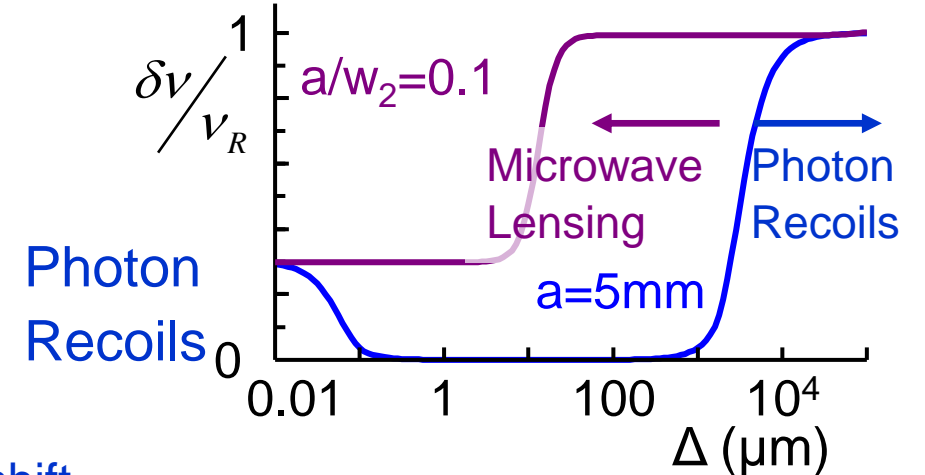

- Consider a single atom traveling on the fountain axis.
  - weak pulses ( $\phi_{\alpha,\beta} \rightarrow 0$ ), 1D, detect right after 2<sup>nd</sup> interaction.
- Only single photon recoils contribute  $\rightarrow$  analytic.

$$\delta v = \frac{1}{2\pi T} \frac{\phi_\alpha \phi_\beta \int_{-a}^a \cos(k_\beta x) \sum_{\pm} \pm e^{-\frac{x^2 \pm v_R x T + \frac{1}{2} v_R^2 T^2}{w_2^2}} \sin\left(w_{12}^2 \frac{k_\alpha x \pm \omega_R T}{w_2^2}\right) dx}{\phi_\alpha \phi_\beta \int_{-a}^a \cos(k_\beta x) \sum_{\pm} e^{-\frac{x^2 \pm v_R x T + \frac{1}{2} v_R^2 T^2}{w_2^2}} \cos\left(w_{12}^2 \frac{k_\alpha x \pm \omega_R T}{w_2^2}\right) dx}$$

$$\frac{w_{12}^2}{w_2^2} = \frac{\frac{\hbar^2}{2m^2 \Delta^2} t_1 t_2 + 2\Delta^2}{\frac{\hbar^2}{2m^2 \Delta^2} t_2^2 + 2\Delta^2}$$

Lensing

- As  $\Delta \rightarrow \infty$ , microwave lensing  $\rightarrow$  the recoil shift (&  $a \rightarrow \infty$ ).
- Confirmation of sign & numerical factors of calculated microwave lensing shift.

# Enhanced Loading with Cd Metastable MOT

- Use only UVA - avoid 229 nm light
- 361 nm meta-stable MOT loading
  - $\sim 10^{10}$  atoms,  $\sim 10\times$  RIKEN 229 nm MOT
  - 361 nm also gives high S/N detection
- Trap all 6 Bosons:  $^{106}\text{Cd}$ ,  $^{108}\text{Cd}$ ,  $^{110}\text{Cd}$ ,  $^{112}\text{Cd}$ ,  $^{114}\text{Cd}$  &  $^{116}\text{Cd}$ 
  - MOT gradient: 5.7 G/cm (170 to 400 G/cm for 229 nm singlet MOT).

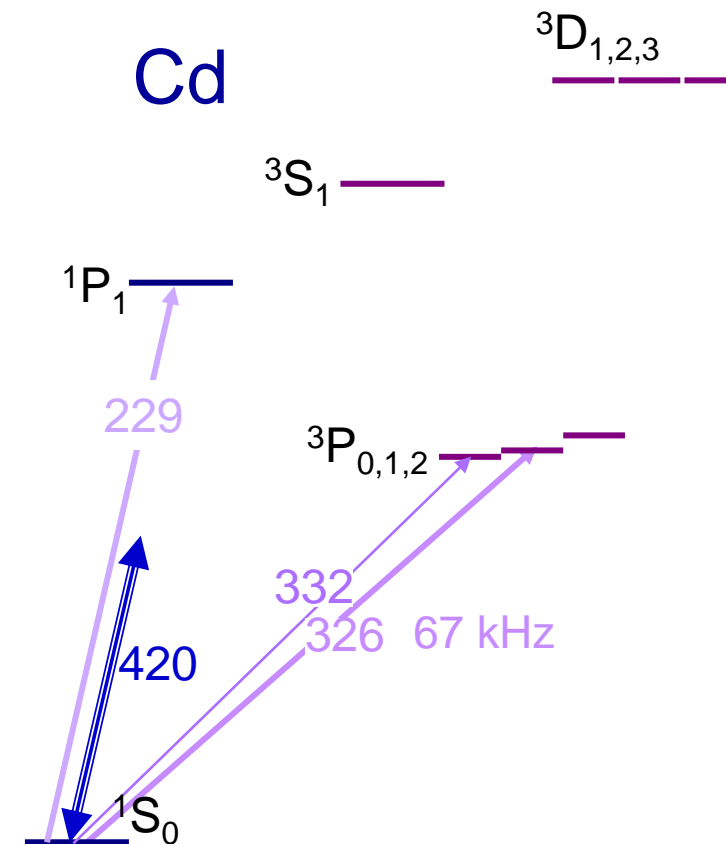

- 2 Fermion spin  $\frac{1}{2}$  isotopes:  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ 
  - Spin  $\frac{1}{2}$  nuclei (& negative magnetic moments)

# Atomic Clock Candidates

- Dominant lattice clock uncertainties have been AC Stark Shifts: from blackbody radiation and higher order shifts from the lattice light.
- Hg, Cd, Zn & Mg have small sensitivities to BBR.

Clock	$\pm 0.1K$ BBR ( $10^{-18}$ )	$^3P_1 \Gamma$ (kHz)	$^3P_1 \lambda$ (nm)	Magic $\lambda_m$ (nm)	# of $l=1/2$ Fermions	$l$ of Fermions	1 mTorr pressure ( $^{\circ}C$ )

# Optical Frequency Atomic Clocks

A comparable S/N and linewidth  $\Delta\nu$  gives optical standards much higher stability.

$$\frac{\delta\nu}{\nu} = \frac{\Delta\nu}{\pi\nu S/N}$$

It has been easier to improve the accuracy of optical clocks more rapidly than for  $\mu$ wave clocks.

- Laser-cooling & fs comb lasers
- Recently contributing to TAI
- Ions: Yb<sup>+</sup>, Al<sup>+</sup>, Hg<sup>+</sup>, In<sup>+</sup>
- <sup>229</sup>Thorium nuclear clock
- Optical lattice clocks.

 Ludlow *et al.*, Rev. Mod. Phys. '15

Yb<sup>+</sup>:  $\pm 3.2 \times 10^{-18}$

Huntemann *et al.*, PRL '16

# Optical Lattice Clocks

- Several choices: Sr, Yb, Hg, Mg, & Cd.
- Sr & Yb lattice clocks report accuracies of  $\pm 10^{-18}$ .
  - Narrow linewidth - 1 mHz (0.1 Hz)
  - Blackbody shifts
  - Lattice light shifts
  - Fermionic isotopes
    - suppressed collision shift

P. Lemonde

Katori *et al.*, PRL '03

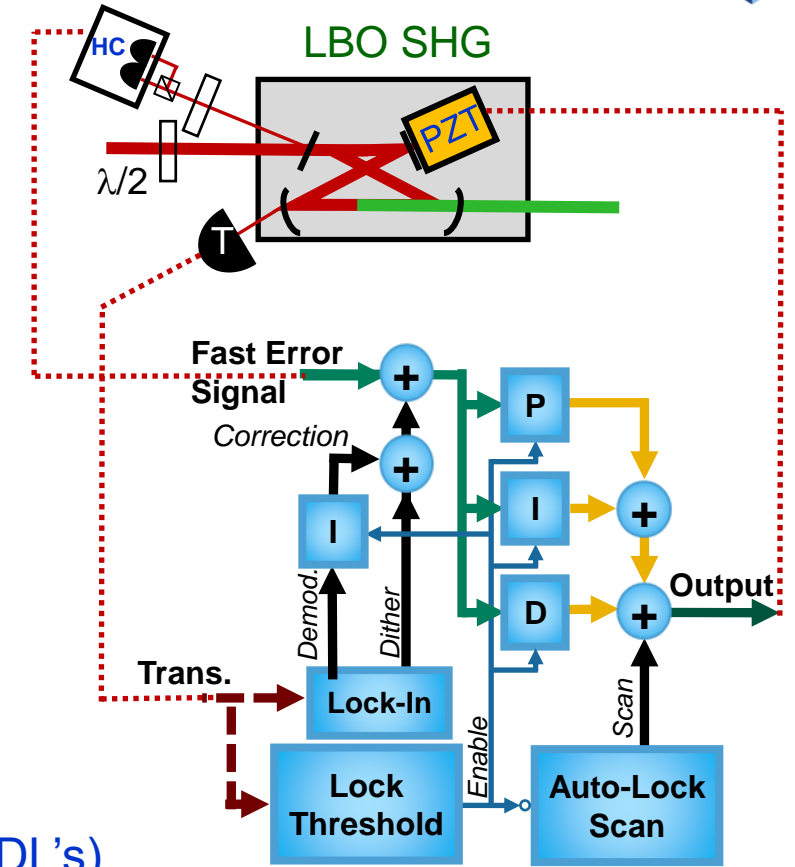

Nicholson ... Ye, Nature Comm. '15

# Enhanced Hänsch-Couillaud Cavity Lock

- Polarization lock – compact & efficient with laser power. Auto-lock using cavity transmission.
- Cavity has to be birefringent.
- Polarization drifts, e.g. temperature dependent birefringence, can produce lock offsets.
- Add small amplitude dither with slow feedback (20 mHz) to correct offset error & drifts.
  - Dither amplitude can be well below the noise level with a kHz bandwidth.
  - Inhibit dither for fluorescence detection.
- Natural to implement with an FPGA – inputs: HC fast error input & cavity transmission for auto-lock
- Rectangular reference cavity:
  - 8 input/output ports
  - birefringence from mirror reflectivities for s & p polarization
- Transmission H-C: spatially filters lasers with *rich* transverse mode structure (TA's & ECDL's).

Hänsch & Couillaud, Opt. Comm. '80

# $^{87}\text{Rb}$ Cold Collision Frequency Shift

- $-0.38(8)\text{mHz}$  @  $n=1.0(6)10^9 \times \text{cm}^{-3}$
- $50\times$  less than  $^{133}\text{Cs}$
- Consistent with calculations
- GPS & SI second

## RECOMMENDATION CCTF 1 (2004):

**Concerning secondary representations of the second**  
The Consultative Committee for Time and Frequency,

... **recommends** that the unperturbed ground-state hyperfine quantum transition of  $^{87}\text{Rb}$  may be used as a secondary representation of the second with a frequency of  $f_{\text{Rb}} = 6\,834\,682\,610.904\,324 \text{ Hz}$  and an estimated relative standard uncertainty ( $1\sigma$ ) of  $3 \times 10^{-15}$ , ... .

## CCTF (2006): recommends

$^{199}\text{Hg}^+$  @ 282nm,  $^{88}\text{Sr}^+$  @ 674nm,  $^{171}\text{Yb}^+$  @ 436nm, &  $^{87}\text{Sr}$  698 nm.

# Optical Clocks

- Fractional frequency is the key performance measure.

$$\nu_{opt} \approx 10^{15} \text{ Hz} \quad 100,000 \times$$

- How do you make a very short pulse of light (sound)?

A laser with a million colors!

$$\frac{\delta\nu}{\nu} = \frac{\Delta\nu}{\pi\nu S/N}$$

**Count optical cycles!**

# Counting the Ticks of Light

$$2f - f = (\text{Pulse Rate}) \times 429,228 = f$$

- Measure  $f$  by measuring the difference between  $f$  &  $2f$ !
- Much better clocks - also large impact on chemistry, astro, ...

# Juggling Atomic Fountains

- State-to-state velocity-selected differential crossed-beam scattering at  $\mu\text{K}$  energies.

$$E_c = \frac{mg^2 \Delta t^2}{4}$$

- Ramsauer-Townsend effect
- Large improvement in clock stability.

# Distinguishable Fermions?

Identical?

$$\frac{|\uparrow\rangle + |\downarrow\rangle}{\sqrt{2}}$$

$$\frac{|\uparrow\rangle - |\downarrow\rangle}{\sqrt{2}}$$

Despite decoherence, Bosons and Fermions often appear to be quantum mechanically identical.

# Ultracold Fermions

- At ultracold temperatures, only s-wave scattering.
- Antisymmetric wavefunction  $\rightarrow$  no scattering of identical fermion superpositions!

- Decoherence  $\rightarrow$  distinguishable fermions  $\rightarrow$  collisions

- No collision shift! Despite being distinguishable, fermions act as if they're indistinguishable!

- $[H_{\text{light}}, V_{\uparrow\downarrow}] = 0 \rightarrow$

**Fermions are Universally Immune to Collisions!**

Zwierlein, Hadzibabic, Gupta, & Ketterle, PRL '03

# Optical-Clock Fermion Collisions

- “Fermions are universally immune to collisions.”
- Campbell ... Ye observed a collision shift for fermions.
- Treated shift as  $\propto n_{\downarrow} - n_{\uparrow}$ .

$$\Delta \nu \stackrel{?}{=} \frac{2\hbar a_{\downarrow\uparrow}}{m} g^{(2)} (n_{\downarrow} - n_{\uparrow})$$

- $[H_{\text{light}}, V_{\downarrow\uparrow}] \neq 0$  for optical fields with fast spatial variations.
- Our theoretical work showed that the Sr & Yb collision shifts are p-wave, not s-wave.

Zwierlein, Hadzibabic, Gupta, & Ketterle, PRL '03

# Fermion Clock Collision Shift

- Many particles are sum of pair-wise effects
- Basis – Singlet and Triplet states of 2 atoms:

$$\Delta\nu = \frac{g}{2\pi} \frac{\sin(2\Delta\theta_1) \sin(\Delta\theta_2) \cos(\bar{\theta}_2)}{\sin(\bar{\theta}_1) \sin(\bar{\theta}_2)}$$

- The light only addresses atom pairs that are identical.

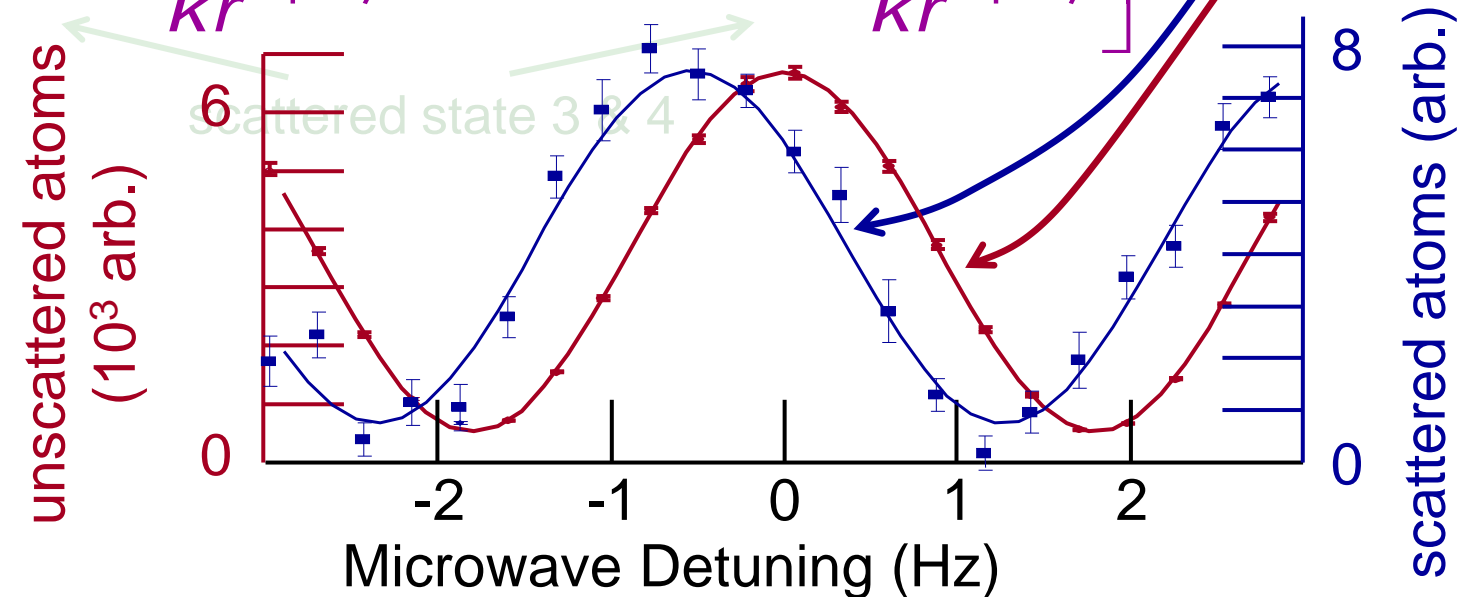

# Precise Measurement of Scattering Phase Shifts

- Juggle atoms by tossing 2 laser-cooled clouds with short delay.
- Launch delays of 7 to 20 ms give ultra-cold scattering, 15 to 200  $\mu\text{K}$ .
- In a clock, a microwave cavity prepares atoms in a coherent superposition and enables a readout of the relative phase of those two clock states.

$$\psi^+ = \frac{1}{\sqrt{2}} \left[ e^{+ikz} (|3\rangle + |4\rangle) \right] + e^{i\delta_3} \sin \delta_3 \frac{e^{ikr}}{kr} |3\rangle + e^{i\delta_4} \sin \delta_4 \frac{e^{ikr}}{kr} |4\rangle$$

- Detect only scattered atoms.

# Precise Measurement of Scattering Phase Shifts

- In scattering measurements, effects are proportional to atomic density.
- Best density measurements are 10%.
- Key is that the relative phase of the clock coherence of the scattered atoms is independent of density.
- Clock accuracy: ppm scattering lengths.
- Sensitive to time variation of  $m_e/m_p$  &  $\alpha$  at a Feshbach resonance.

# Cd Optical Lattice Clock

- Hg, Cd, & Mg have small sensitivities to BBR shifts.
- 2 Fermion spin 1/2 isotopes,  $^{111}\text{Cd}$  &  $^{113}\text{Cd}$ 
  - select scattering lengths.
  - 6 Bosons:  $^{106}\text{Cd}$ ,  $^{108}\text{Cd}$ ,  $^{110}\text{Cd}$ ,  $^{112}\text{Cd}$ ,  $^{114}\text{Cd}$ ,  $^{116}\text{Cd}$ .
- Wavelengths and Doppler/sideband cooling are easier for Cd than Hg.
- Elegant scheme to generate all wavelengths.

A. Yamaguchi, KG, & H. Katori
