$$\dot{y} = [\omega x + \mu y - (x + y^2)x]dt + \sigma dW(t)$$

 $\mu$  is the amplification rate.

limit cycle: 
$$x(t) = \sqrt{\mu} \cos(\theta(t)), \quad y(t) = \sqrt{\mu} \sin(\theta(t)).$$
  
$$d\theta(t) = \omega + \frac{\sigma}{\mu} dW(t)$$

#### the larger the limit cycle the slower the phase noise.

See Aminzare et al. IEEE 58th Conference on Decision and Control (CDC), 2019.

# Phase reduction and noise.

First passage time distribution: probability for time *T* taken for phase to change by  $2\pi$ ... the period is a random variable.

Gerard Milburn<sup>1</sup> and Michael Kewming<sup>2</sup>. (20Stochastic quantum thermodynamics of cl

・ロト ・ 一下・ ・ ヨト・

First passage time distribution: probability for time *T* taken for phase to change by  $2\pi$ ... the period is a random variable.

Wald or Inverse Gaussian distribution of periods.

$$W(T, \alpha, \lambda) = \sqrt{\frac{\lambda}{2\pi}} T^{-3/2} \exp\left[-\frac{\lambda}{2\alpha^2 T} (T-\alpha)^2\right] \quad t \ge 0.$$

イロト イポト イモト イモト

where  $\alpha, \lambda$  are positive real parameters ( $\lambda$  is called the spread parameter).

First passage time distribution: probability for time T taken for phase to change by  $2\pi$ ... the period is a random variable.

Wald or Inverse Gaussian distribution of periods.

$$W(T, \alpha, \lambda) = \sqrt{\frac{\lambda}{2\pi}} T^{-3/2} \exp\left[-\frac{\lambda}{2\alpha^2 T} (T-\alpha)^2\right] \quad t \ge 0.$$

where  $\alpha$ ,  $\lambda$  are positive real parameters ( $\lambda$  is called the spread parameter).

$$\overline{T} = \alpha$$
$$\overline{\Delta T^2} = \frac{\alpha^3}{\lambda}$$

イロト イポト イモト イモト

Normal form limit cycle:

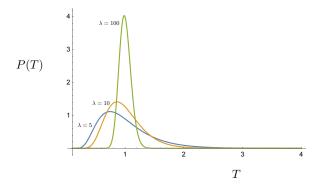

$$\overline{T} = rac{2\pi}{\omega}$$
 $\overline{\Delta T^2} = rac{2\pi\sigma^2}{\omega^3\mu}$ 

fluctuations in period get smaller as the limit cycle gets bigger.

More work, more heat dissipated, better the clock (See Erker et al. 2017).

A (10) × A (10) × A (10) ×

## Noise and fluctuations in period.

Mean period  $\overline{T} = 1$  and three different values of the spread parameter,  $\lambda$ . Increasing  $\lambda$  is decreasing noise.

Quantum clocks & and measurement noise.

#### Quantum clocks & and measurement noise.

Gerard Milburn<sup>1</sup> and Michael Kewming<sup>2</sup>. (20Stochastic quantum thermodynamics of cl

### Example: the laser.

A laser is a quantum clock, if you add a counter.

Gerard Milburn<sup>1</sup> and Michael Kewming<sup>2</sup>. (20Stochastic quantum thermodynamics of cl

## Example: the laser.

A laser is a quantum clock, if you add a counter.

Dissipative nonlinear oscillator (Wiseman, PRA, 60, 4083).

$$\dot{\rho} = Gn_{s}\mathcal{D}[a^{\dagger}] \left( \mathcal{A}[a^{\dagger}] + n_{s} \right)^{-1} \rho + \kappa \mathcal{D}[a]\rho$$

$$\mathcal{D}[a]
ho = a
ho a^{\dagger} - rac{1}{2}(a^{\dagger}a
ho + 
ho a^{\dagger}a) \quad \mathcal{A}[a]
ho = rac{1}{2}(a^{\dagger}a
ho + 
ho a^{\dagger}a)$$

*G* is the small signal gain,  $n_s$  saturation photon number and  $\kappa$  is the cavity decay rate.

#### Equivalent classical model

Dynamics of the average field  $\alpha(t) = tr(a\rho(t))$ 

$$\dot{\alpha} = -\frac{\kappa\alpha}{2} \left( 1 - \frac{Gn_s}{\kappa(|\alpha|^2 + n_s)} \right)$$

Well above threshold this is similar to the van der Pol oscillator in a rotating frame.

There are two fixed points  $\alpha_0 = 0$  and  $|\alpha_0|^2 = Gn_s/\kappa$  for  $G >> \kappa$ . The second solution is the above threshold limit-cycle solution.

Quantum clocks & and measurement noise.

## Quantum model

What to measure?

## Quantum model

What to measure?

Photon counting ? .... a Poisson distribution of counts. No oscillatory clock signal.

No point in measuring output intensity.

Measure field amplitude by heterodyne detection to get a clock signal.

Measure field amplitude by heterodyne detection to get a clock signal.

measured current:

$$J_{het}(t) dt = \kappa \langle a(t) 
angle_c dt + \sqrt{rac{\kappa}{\eta}} dW(t)$$

where  $0 < \eta \le 1$  is the photo-detector quantum efficiency, dW(t) is a complex valued Weiner process and  $\langle a(t) \rangle_c$  is the mean field amplitude conditioned on the entire history of the observed current.

A (10) × (10)

Conditional quantum dynamics:

$$d
ho_{c} = \mathcal{L}
ho_{c}dt + \sqrt{rac{\eta}{\kappa}}\mathcal{H}[a]
ho_{c}dW^{*}$$

 $dW^*$ , complex Weiner increment,  $\mathcal{H}[A]$  is defined by

$$\mathcal{H}[\mathcal{A}]\rho = \mathcal{A}\rho + \rho \mathcal{A} - \mathrm{tr}[\mathcal{A}\rho + \rho \mathcal{A}]\rho$$

- 4 個 ト 4 ヨ ト 4 ヨ ト -

is nonlinear...as expected.

Wiseman and Milburn "Quantum Measurement and Control, CUP, 2011

Well above threshold (on the classical limit cycle)

$$\dot{
ho}_{c} = \Gamma \mathcal{D}[\boldsymbol{a}^{\dagger}\boldsymbol{a}] + \sqrt{\eta}\mathcal{H}[\boldsymbol{a}]
ho_{c}\boldsymbol{dW}^{*}$$

non-thermal phase diffusion rate  $\Gamma = \kappa/2\bar{n}$ .

Well above threshold ( on the classical limit cycle)

$$\dot{
ho}_{c} = \Gamma \mathcal{D}[\boldsymbol{a}^{\dagger}\boldsymbol{a}] + \sqrt{\eta}\mathcal{H}[\boldsymbol{a}]
ho_{c}\boldsymbol{dW}^{*}$$

Writing  $\rho_c(t)$  as a mixture of coherent states as

$$\rho_{c}(t) = \int d^{2}\alpha P_{c}(\alpha, t) |\alpha\rangle \langle \alpha |$$

define  $\alpha = re^{i\phi}$ 

$$d\phi_c = \sqrt{\Gamma} dW$$

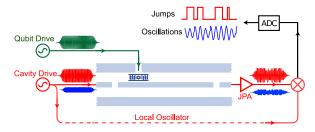

non-thermal phase diffusion rate  $\Gamma = \kappa/2\bar{n}$ . Energy dissipated by cavity loss is  $\propto \kappa \bar{n}$  Experiment using a superconducting circuit qubit.

Experiment using a superconducting circuit qubit.

Gerard Milburn<sup>1</sup> and Michael Kewming<sup>2</sup>. (20Stochastic quantum thermodynamics of cl

э

Simple model:

- Transmon qubit dispersively coupled to a superconducting microwave cavity.
- Cavity and qubit are driven coherently.
- The output field is subject to a homodyne measurement.

$$d\rho_{c} = \underbrace{-iE[a + a^{\dagger}, \rho_{c}]dt}_{-i\chi[a^{\dagger} a\sigma_{z}, \rho_{c}]dt} \underbrace{\operatorname{qubit drive}}_{i\Omega[\sigma_{x}, \rho_{c}]dt} \\ +\sqrt{\eta\kappa}\mathcal{H}[a]\rho_{c}dW(t).$$

 $\chi$ : dispersive coupling.  $\gamma$ : qubit amplitude damping rate,  $\kappa$ : cavity damping rate,  $\eta$  photodetector, efficiency

$$\mathcal{D}[A]$$
 and  $\mathcal{H}[A]$  are superoperators:  
 $\mathcal{D}[A]\rho = A\rho A^{\dagger} - \frac{1}{2}(A^{\dagger}A\rho + \rho A^{\dagger}A)$  and  
 $\mathcal{H}[A]\rho = A\rho + \rho A^{\dagger} - \operatorname{tr}(A\rho + \rho A^{\dagger})\rho.$ 

Adiabatically eliminate the cavity field. conditional master equation for the reduced state of the qubit ( $\rho_{\sigma}$ ) only:

$$d\rho_{\sigma} = -i[H_{\sigma}, \rho_{\sigma}]dt + \gamma \mathcal{D}[\sigma_{-}]\rho_{\sigma}dt + \Gamma \mathcal{D}[\sigma_{z}]\rho_{\sigma}dt - \sqrt{\Gamma}\mathcal{H}[\sigma_{z}]\rho_{\sigma}dW(t).$$

Here  $H_{\sigma} = \Omega \sigma_x + \Delta \sigma_z$ 

$$\frac{\Gamma}{\kappa} = 4 \left(\frac{\chi}{\kappa}\right)^2 n_0 \text{ measurement dephasing rate}$$
$$\frac{\Delta}{\kappa} = \left(\frac{\chi}{\kappa}\right) n_0 \text{ effective Stark shift}$$

A D > A B > A B > A B >

$$n = |lpha_0|^2 = 4|E|^2/\kappa$$

 $\Gamma$  can be tuned by varying *E*.

Bloch sphere conditional dynamics.

$$dX = -2\Delta Y dt - \gamma_2 X dt$$
  

$$dY = 2\Delta X dt - 2\Omega Z dt - \gamma_2 Y dt$$
  

$$dZ = 2\Omega Y dt - \gamma (1+Z) dt - 2\sqrt{\Gamma}(1-Z^2) dW$$

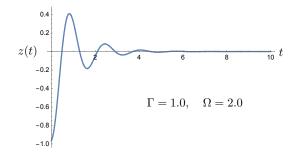

where  $\gamma_2 = \gamma/2 + 2\Gamma$  is the transverse decay rate of the conditional polarization.

Spontaneous emission rate,  $\gamma \ll 1$ , so  $\gamma_2 \approx 2\Gamma$ .

The unconditional dynamics is obtained by averaging over the noise.  $\overline{dW} = 0$ .

イロト イヨト イヨト イヨト

#### Conclusions.

- All clocks are dissipative systems pushed away from thermal equilibrium by work or measurement.
- At low temperature, weak continuous measurement plays a special role to extract a clock signal.
- At low temperature, quantum noise (spontaneous emission, tunnelling, measurement back action) limits clock accuracy.

- Use coherent quantum feedback.
- Engineer quantum noise for better clocks

(eg Wiseman, et al. The Heisenberg limit for laser coherence, Nat. Phys. (2021).
