P-wave Production in NRQCD

- *P*-wave (χ_c, χ_b) production at LO in v :

**Bodwin, Braaten, Lepage,
PRD51, 1125 (1995)**

$$\sigma[\chi_{QJ}(P)] = (2J+1)\left(c_{3P_J^{[1]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle + c_{3S_1^{[8]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle \right)$$

(Q=c **or** b)

**short-distance coefficients,
generally available to NLO**

- $c_{3P_J^{[1]}}(P)$ and $c_{3S_1^{[8]}}(P)$ describe perturbative production of $Q\bar{Q}$. Matrix elements (ME) $\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle$ and $\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle$ describe nonperturbative evolution of $Q\bar{Q}$ into quarkonium.

- Color-octet matrix elements are obtained from fits to data, which depend on normalization and p_T dependence of cross section.

- p_T shapes of cross sections come from $c_{3P_J^{[1]}}(P)$ and $c_{3S_1^{[8]}}(P)$. Fixed-order calculations are known to have difficulty describing cross sections over a wide range of p_T.

P-wave Production in NRQCD

- *P*-wave (χ_c, χ_b) production at LO in v :

$$\sigma[\chi_{QJ}(P)] = (2J+1)\left(c_{3P_J^{[1]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle + c_{3S_1^{[8]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle\right)$$

- $\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle$: color-singlet $Q\bar{Q}$ evolve into χ_Q **(with or without soft radiation)**
  $\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle$: color-octet $Q\bar{Q}$ evolve into χ_Q by soft radiation.

- Color-octet $Q\bar{Q}$ can also evolve into color-singlet $Q\bar{Q}$ by soft radiation before evolving into χ_Q.

  Two channels mix by soft gluon emission due to renormalization:

$$\left(\frac{d}{d\log\Lambda}c_{3P_J^{[1]}}(P)\right)\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle + c_{3S_1^{[8]}}(P)\left(\frac{d}{d\log\Lambda}\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle\right) = 0$$

  **scale dependence
  of short-distance coefficient**
  **scale dependence of
  renormalized color-octet ME**

- Same form of mixing happens for S-wave quarkonium production (ψ, Υ) between color-octet ^3P_J and $^3S_1$ states

Mixing in *P*-wave Production

- Mixing in dimensional regularization $d{=}4{-}2$ ϵ:

vanishes for $l{>}l_{\max}$

$$\left[{}^3S_1^{[8]} \xrightarrow{\quad} {}^3P_J^{[1]}\right] + \left[{}^3S_1^{[8]} \xrightarrow{\quad l} {}^3P_J^{[1]}\right] \propto \int_0^\infty \frac{d|\boldsymbol{l}|}{|\boldsymbol{l}|^{1+2\epsilon}} c_{3S_1^{[8]}}(P{+}l)$$

- $$\int_0^{|\boldsymbol{l}_{\max}|} \frac{d|\boldsymbol{l}|}{|\boldsymbol{l}|^{1+2\epsilon}} c_{3S_1^{[8]}}(P{+}l) = -\frac{|\boldsymbol{l}_{\max}|^{-2\epsilon}}{2\epsilon_{\mathsf{IR}}} c_{3S_1^{[8]}}(P)$$

  IR pole at $l{=}0$ produces scale dependence

  $$+ \int_0^{|\boldsymbol{l}_{\max}|} \frac{d|\boldsymbol{l}|}{|\boldsymbol{l}|} \left[c_{3S_1^{[8]}}(P{+}l) - c_{3S_1^{[8]}}(P) \right]$$
  $$+ O(\epsilon)$$

  plus distribution, singular at $l{=}0$

- Gluon momentum $l{>}0$ is included in the perturbative short-distance coefficient, while only $l{=}0$ is included in the nonperturbative ME. *However, nonperturbative soft gluons can have **nonzero momentum**.*
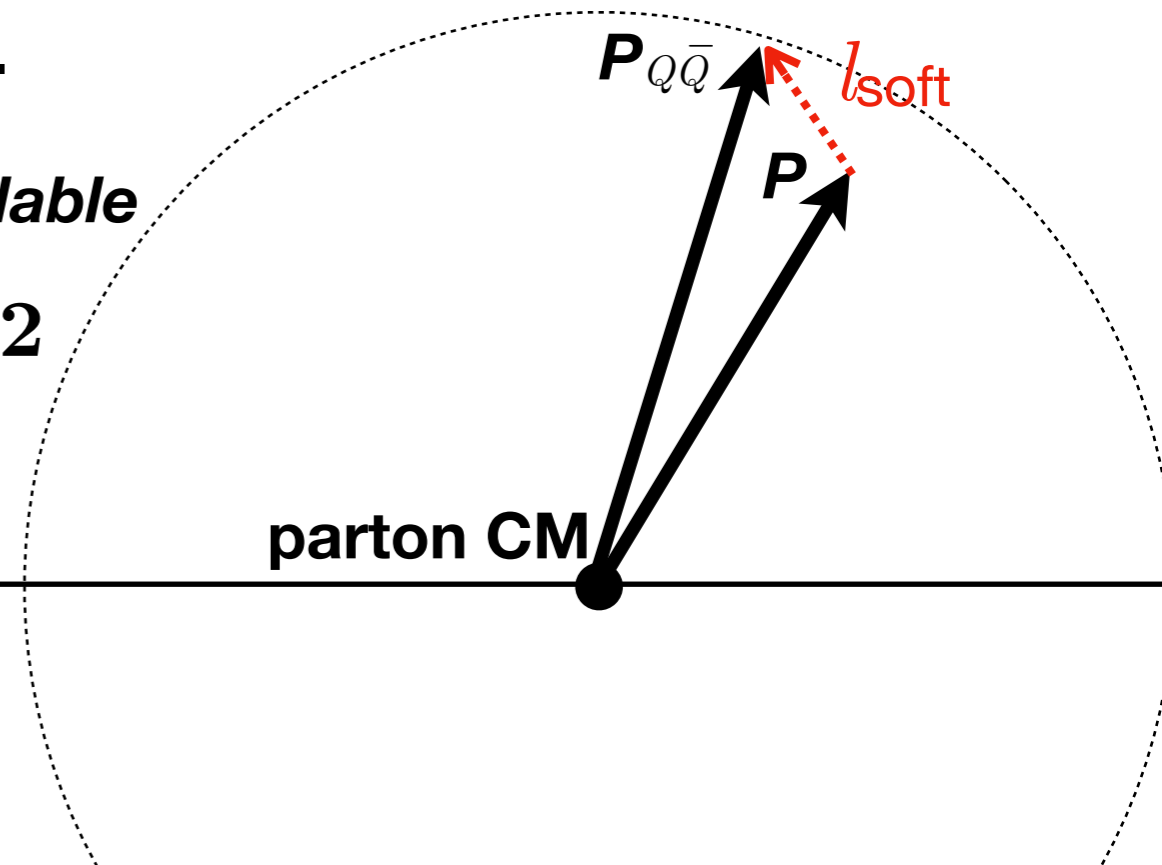

Production Kinematics

- *Nonzero soft gluon momentum* implies that *quarkonium momentum is smaller than $Q\bar{Q}$ momentum*

- In large-p_T hadroproduction, $|\boldsymbol{P}_{Q\bar{Q}}| \lesssim x_1 x_2 \sqrt{s}/2$
  Cross section is sensitive to small changes in Bjorken x.
  $Q\bar{Q}$ cross section is singular at maximum $\boldsymbol{P}$ (l_{soft}=0).
  Hence, quarkonium cross section can be **sensitive to soft gluon momentum.**

Maximum available momentum
$\approx x_1 x_2 \sqrt{s}/2$

$\boldsymbol{P}_{Q\bar{Q}}$ l_{soft}

$\boldsymbol{P}$

Beam axis   **parton CM**

5

Production Kinematics

- Soft radiation is "soft ($\sim mv$)" in the quarkonium rest frame.
  Need to boost from quarkonium rest frame to CM frame.
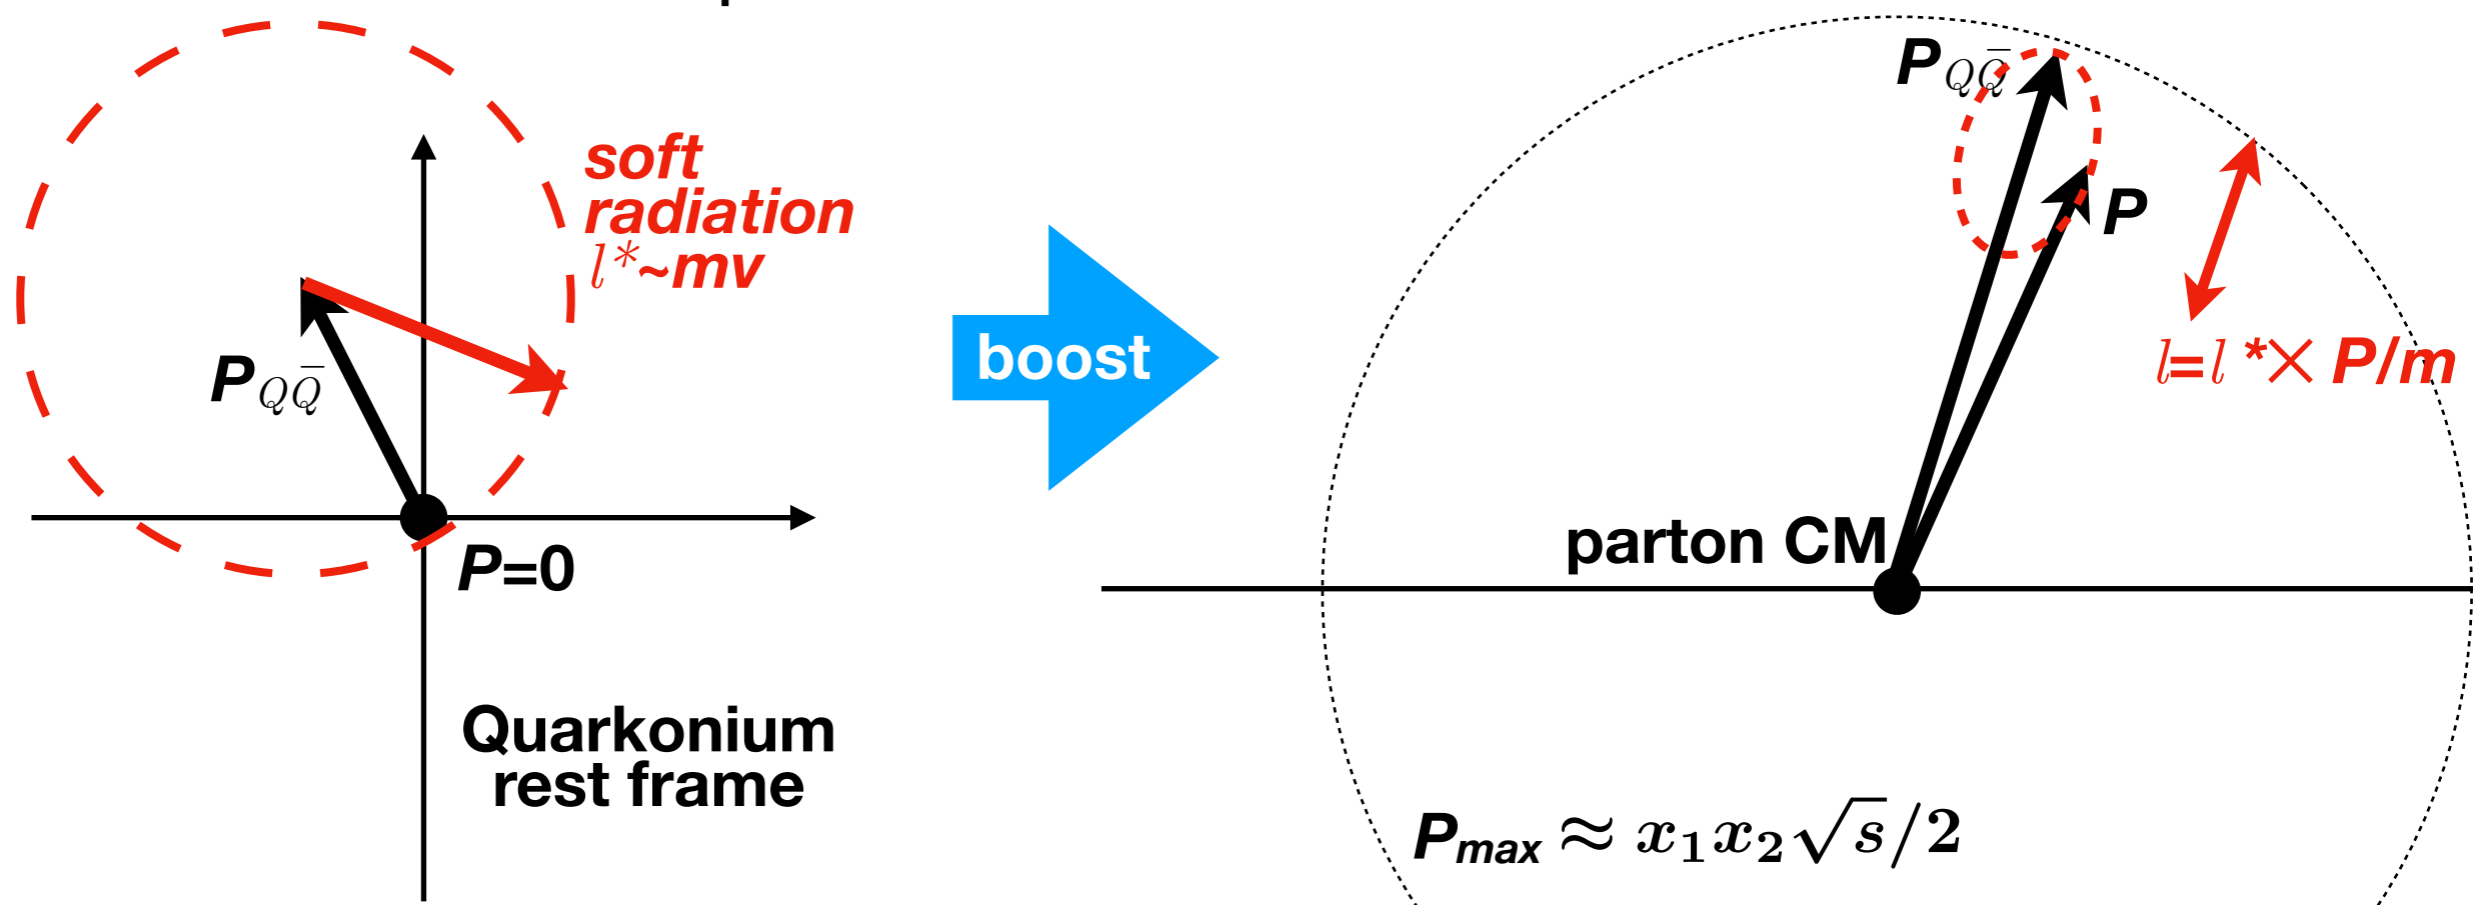

- Soft radiation has *no preferred direction in the **P=0** rest frame*, but after a large boost ($P \gg m_\chi$) the only relevant direction of soft radiation is *lightlike* and *anti-parallel* to **P**. *This effect can be resummed!*

6

Shape Functions

- Schematic form of lowest-dimensional NRQCD matrix elements, defined in quarkonium rest frame:

$$\langle \mathcal{O}^{\chi_Q}(\Gamma) \rangle = \langle \chi^\dagger \Gamma \psi \mathcal{P}_{\chi_Q} \psi^\dagger \Gamma \chi \rangle$$

some combination of Pauli and color matrices, covariant derivatives

- We can have operator matrix elements that read off the $Q\bar{Q}$ momentum in a specific direction l given by

$$\langle \chi^\dagger \Gamma \psi \mathcal{P}_{\chi_Q} (l \cdot D)^n \psi^\dagger \Gamma \chi \rangle$$

- These matrix elements are generated by the "shape function"

$$\mathcal{S}^{\chi_Q}_\Gamma(l_+) = \langle \chi^\dagger \Gamma \psi \mathcal{P}_{\chi_Q} \delta(l_+ - iD_+) \psi^\dagger \Gamma \chi \rangle$$

- In practice, we only need color-octet shape functions, because due to vacuum-saturation approximation, color-singlet shape functions are trivial : $\mathcal{S}^{\chi_Q}_{\Gamma_{\text{singlet}}}(l_+) = \langle \mathcal{O}^{\chi_Q}(\Gamma_{\text{singlet}}) \rangle \delta(l_+)$

7

Shape Function Formalism

- NRQCD formalism :

$$\sigma[\chi_{QJ}(P)] = (2J+1)\left(c_{3P_J^{[1]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle + c_{3S_1^{[8]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle\right)$$

- Shape function formalism (NRQCD with kinematical corrections) :

$$\sigma[\chi_{QJ}(P)] = (2J+1)\left(s_{3P_J^{[1]}}(P)\langle\mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]})\rangle\right.$$

$l=$**momentum lost by soft radiation**

$$\left. + \int_0^\infty dl_+ \, s_{3S_1^{[8]}}(P+l)\mathcal{S}^{\chi_{Q0}}_{3S_1^{[8]}}(l_+)\right)$$

- Formally $\displaystyle\int_0^\infty dl_+ \mathcal{S}^{\chi_{Q0}}_{3S_1^{[8]}}(l_+) = \langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle$,

  but both sides are UV divergent and require renormalization.

- Knowledge of the nonperturbative shape function $\mathcal{S}^{\chi_{Q0}}_{3S_1^{[8]}}(l_+)$ needed to compute cross sections.

Beneke, Rothstein, Wise, PLB408 (1997) 373
Fleming, Leibovich, Mehen, PRD68, 094011 (2003)

Renormalization

- Renormalization of color-octet matrix element
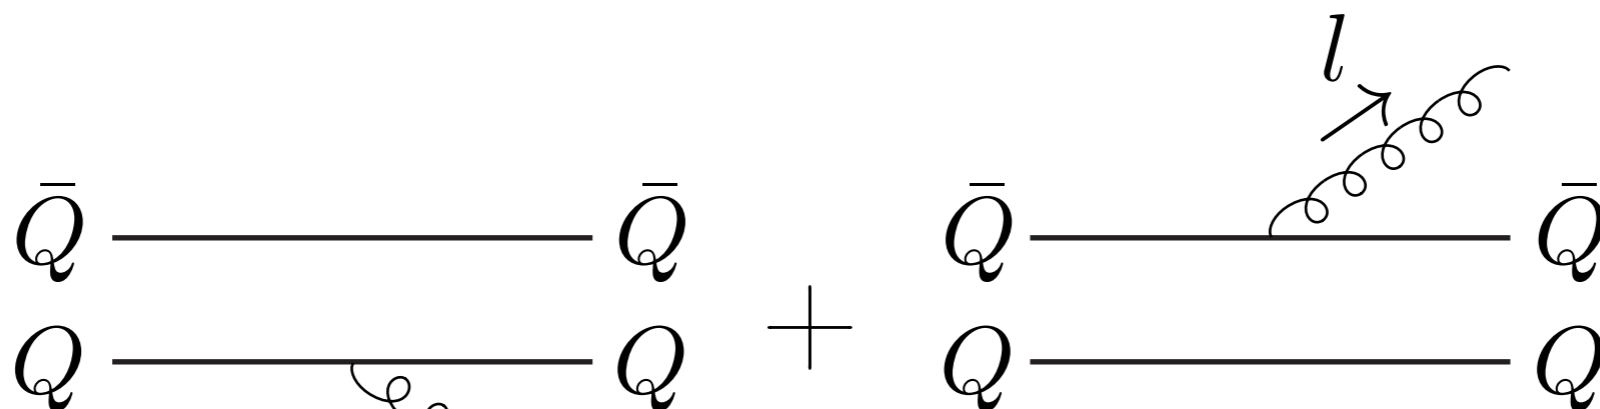

$$\langle \mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]}) \rangle \big|_{\mathrm{UV}} = \langle \mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]}) \rangle \frac{4\alpha_s C_F}{3N_c \pi m^2} \int_0^\infty \frac{dl_+}{l_+^{1+2\epsilon}}$$

- Normalization of the shape function must reproduce this integral. This gives the asymptotic behavior at large l_+

$$\mathcal{S}^{\chi_{Q0}}_{^3S_1^{[8]}}(l_+) \big|_{\mathrm{asy},\, d=4} = \langle \mathcal{O}^{\chi_{Q0}}(^3P_0^{[1]}) \rangle \times \frac{4\alpha_s C_F}{3N_c \pi m^2} \frac{1}{l_+}$$

Nonperturbative Shape Function

- *Asymptotic behavior* from *renormalization*:

$$\frac{d}{d\log\Lambda}\int_0^\Lambda dl_+ \mathcal{S}^{\chi_{Q0}}_{^3S_1^{[8]}}(l_+) = \frac{d}{d\log\Lambda}\langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle^{(\Lambda)}|_{\text{renormalized}}$$

- Nonperturbative normalization must be *IR finite*:

$$\int_0^\infty dl_+ \mathcal{S}^{\chi_{Q0}}_{^3S_1^{[8]}}(l_+) = \langle\mathcal{O}^{\chi_{Q0}}(^3S_1^{[8]})\rangle|_{\text{bare}}$$

- Form of nonperturbative shape function is strongly constrained from *renormalization* and *IR finiteness*.
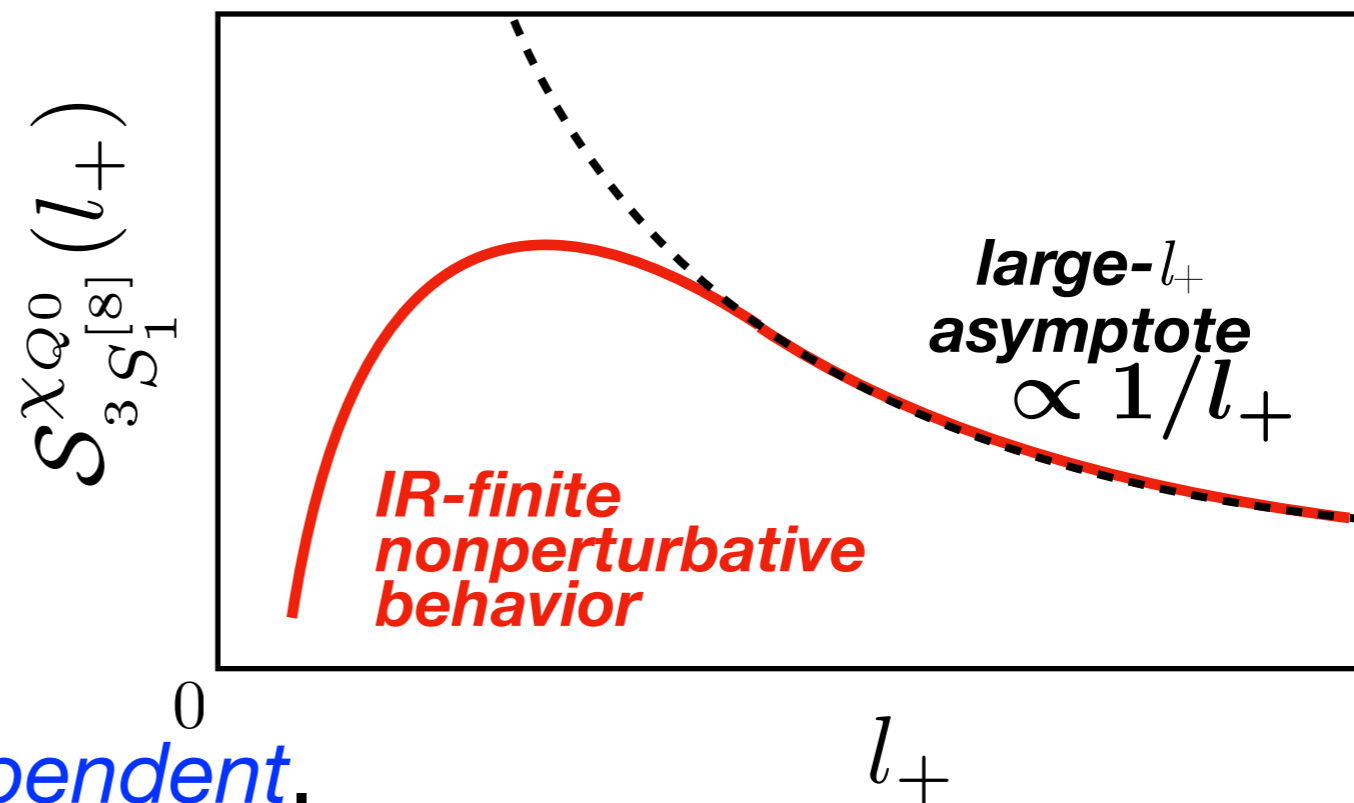

- $l_+\to0$ behavior is *model dependent*.

Corrections to Cross Section

- *P*-wave short-distance coefficients have plus distributions with large subtractions, and color-singlet production rates are negative.

$$\int_0^{l_+^{\max}} \frac{dl_+}{l_+^{1+2\epsilon}} c_{3S_1^{[8]}}(P+l) = -\frac{(l_+^{\max})^{-2\epsilon}}{2\epsilon} c_{3S_1^{[8]}}(P)$$

negative

$$+ \int_0^{l_+^{\max}} \frac{dl_+}{l_+} \left[c_{3S_1^{[8]}}(P+l) - c_{3S_1^{[8]}}(P) \right]$$

- Nonperturbative shape function makes subtractions softer at $l_+=0$, color-singlet cross section is *less negative*

- *Hence, nonperturbative effects* enhance large-p_T cross section

$S_{3S_1^{[8]}}^{\chi_{Q0}}(l_+)$

large-l_+ asymptote $\propto 1/l_+$

IR-finite nonperturbative behavior

0

l_+

11
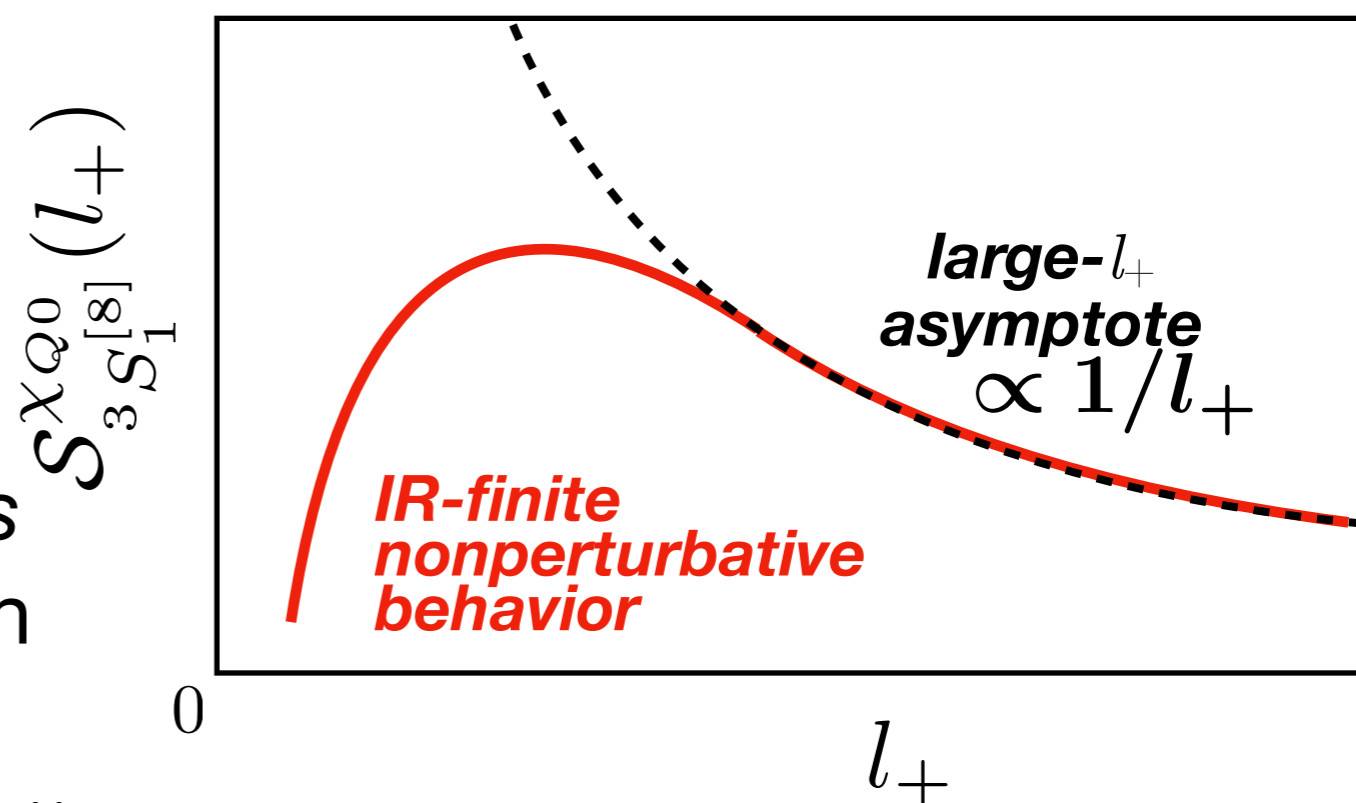

Models for Shape Function

- We can constrain models for the color-octet shape function using the asymptotic form and the normalization condition:

- $l_+ \to 0$ behavior is not strongly constrained, but it should not diverge like $1/l_+$ to ensure the IR-finiteness of the color-octet ME.

- All models shown here reproduce the color-octet matrix elements from NLO fits.
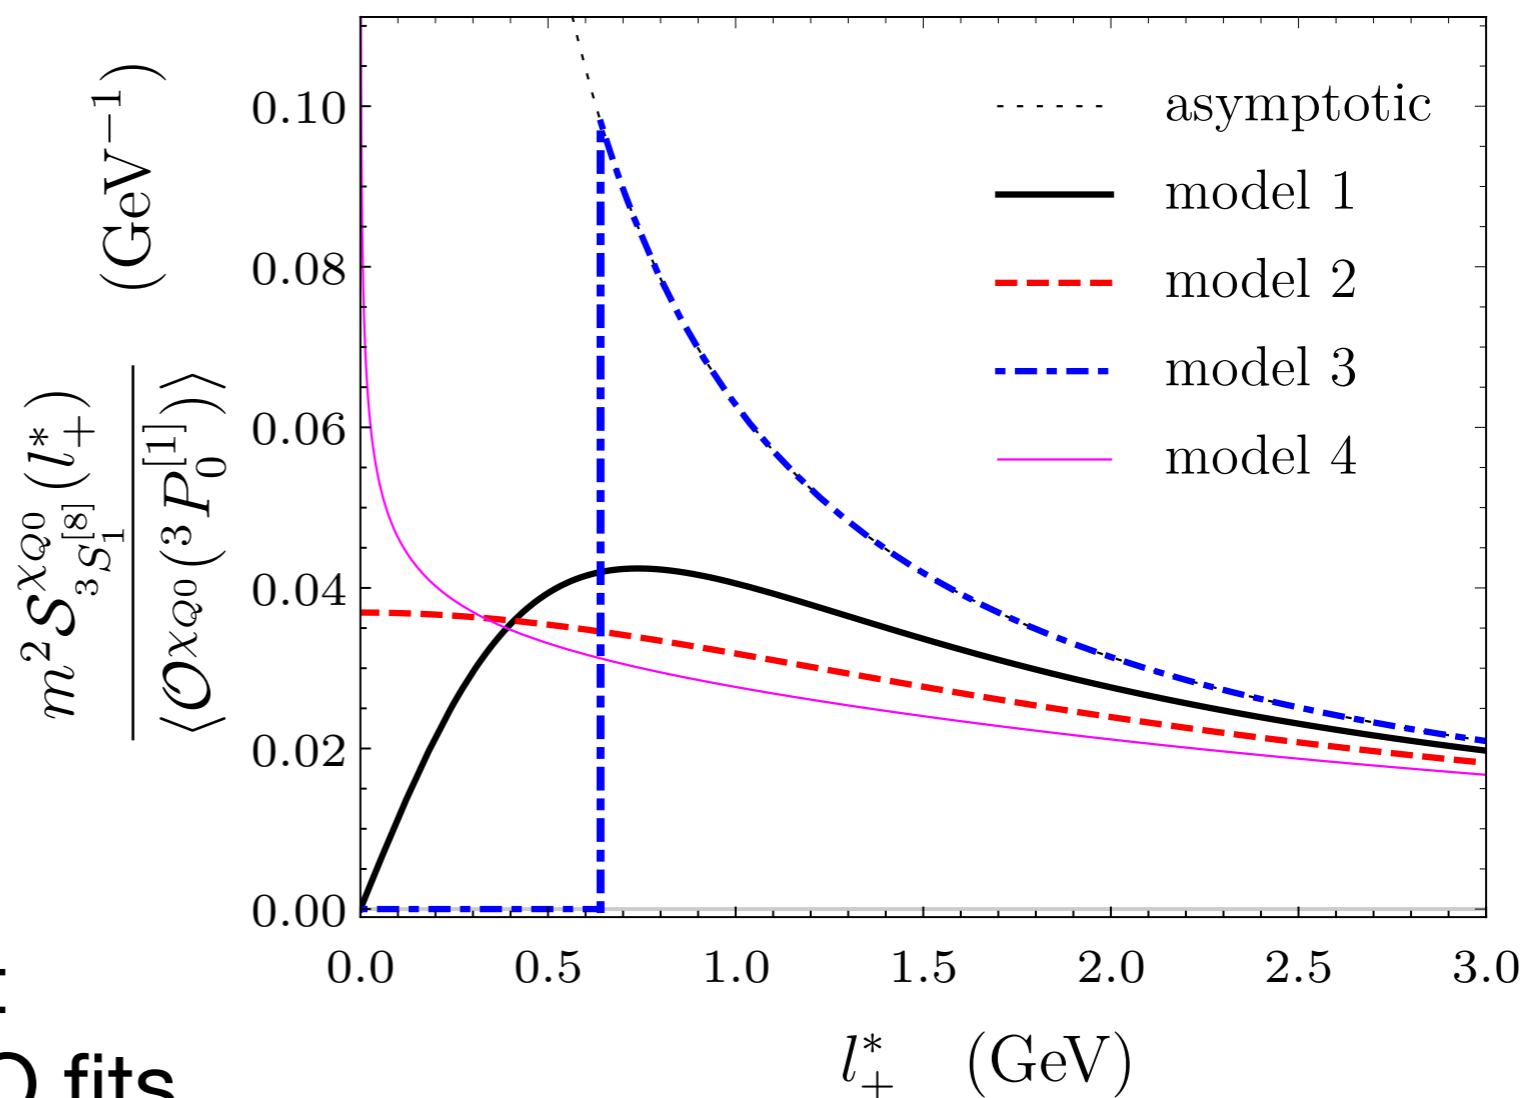

Corrections to Cross Section

- Nonperturbative corrections are almost independent of model.

$$r = \frac{\text{octet cross section in shape function formalism}}{\text{octet cross section in NRQCD}}$$
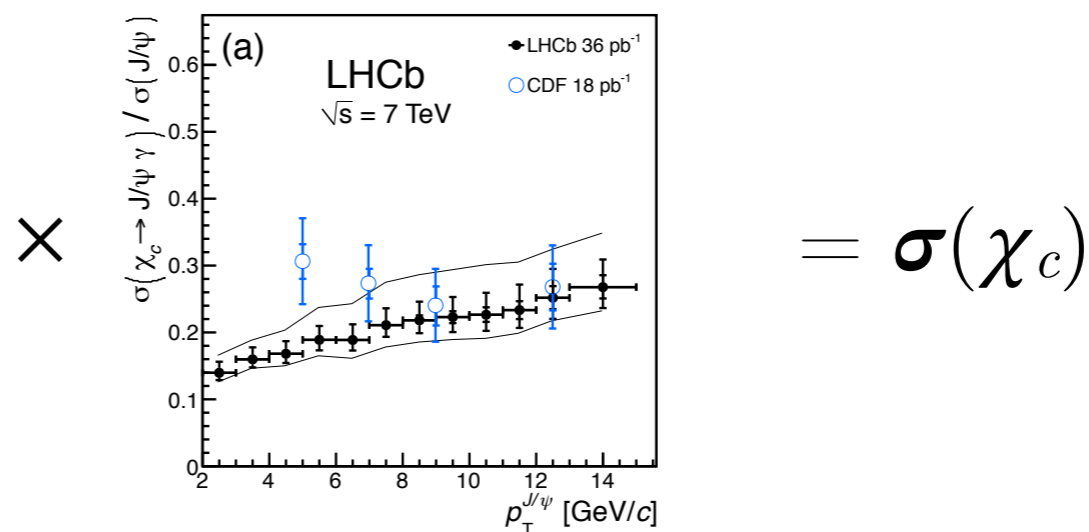

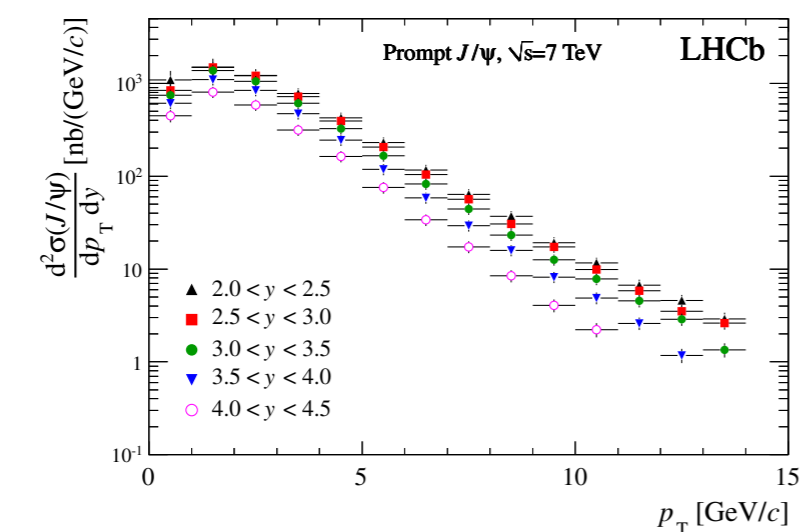

- Ratio is constant at large p_T, and diminish as p_T decreases.

- Overall normalization decrease due to use of quarkonium mass instead of quark pole mass
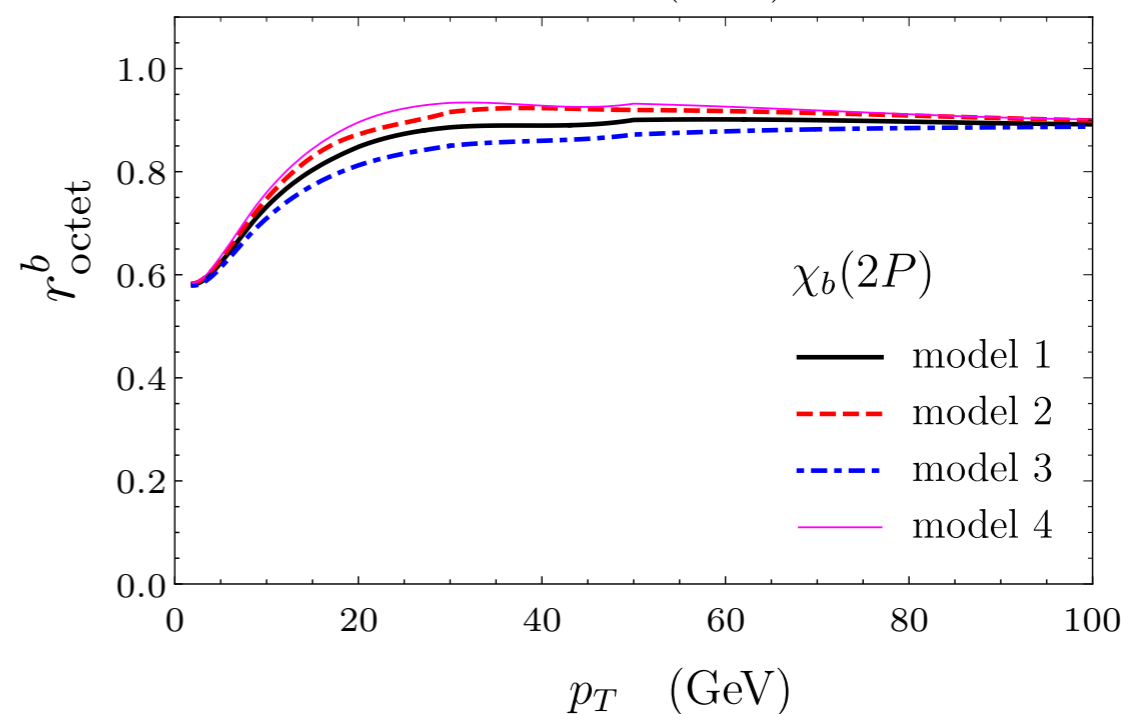

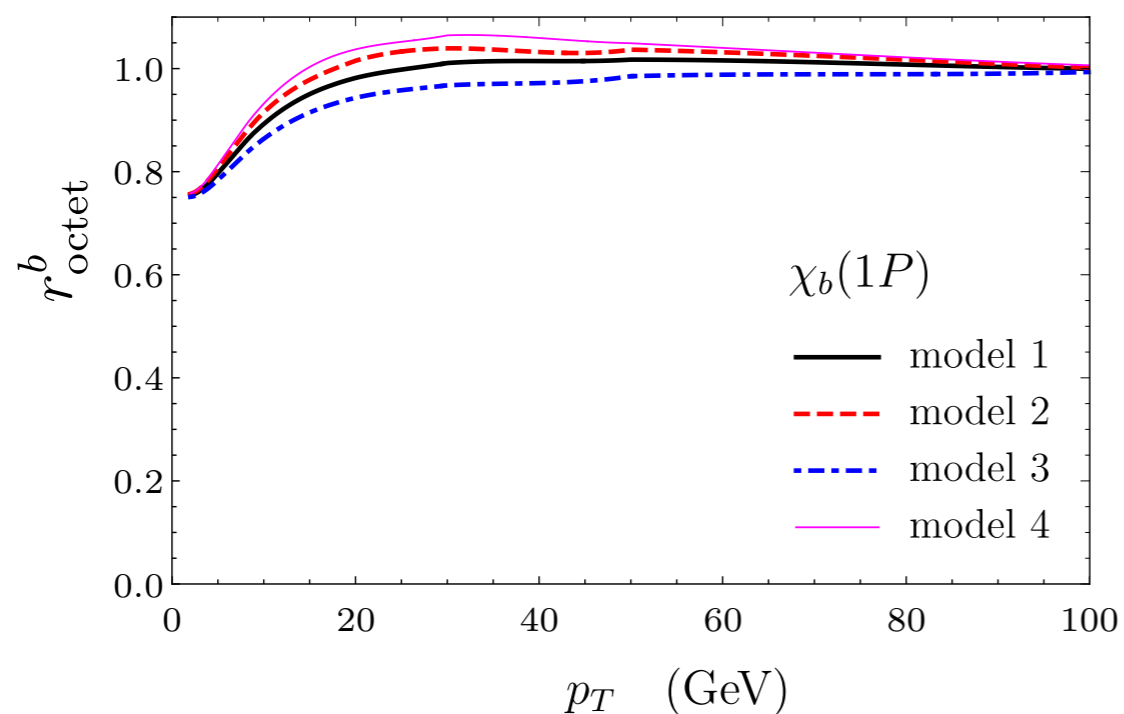

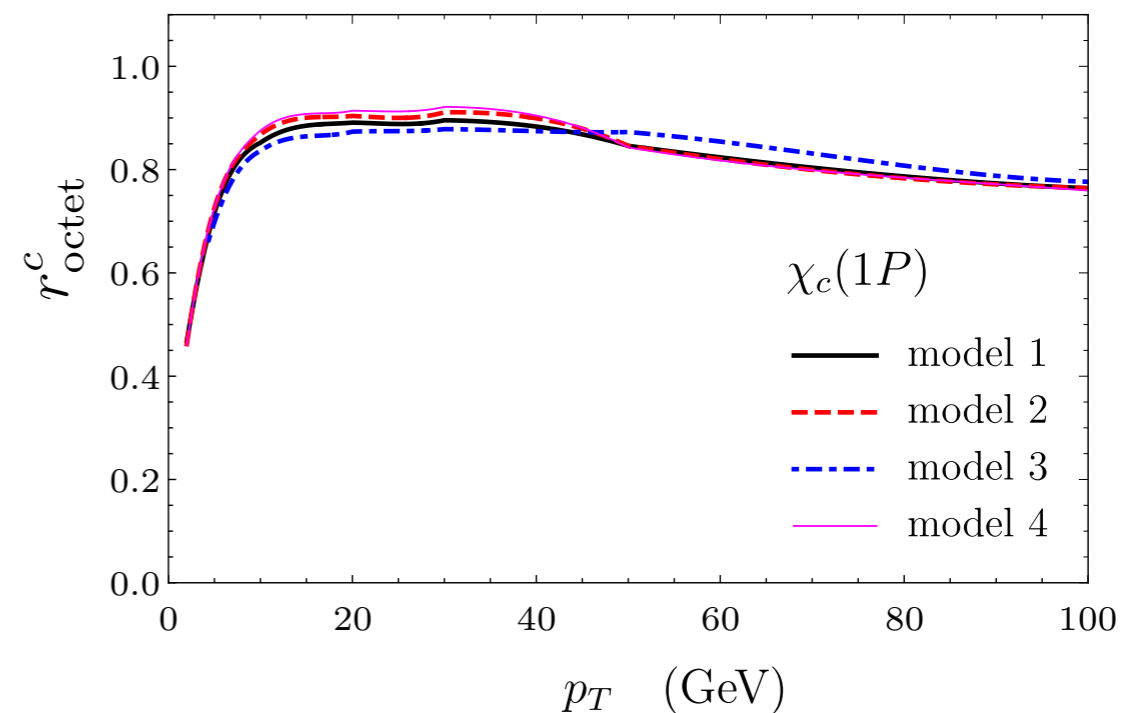

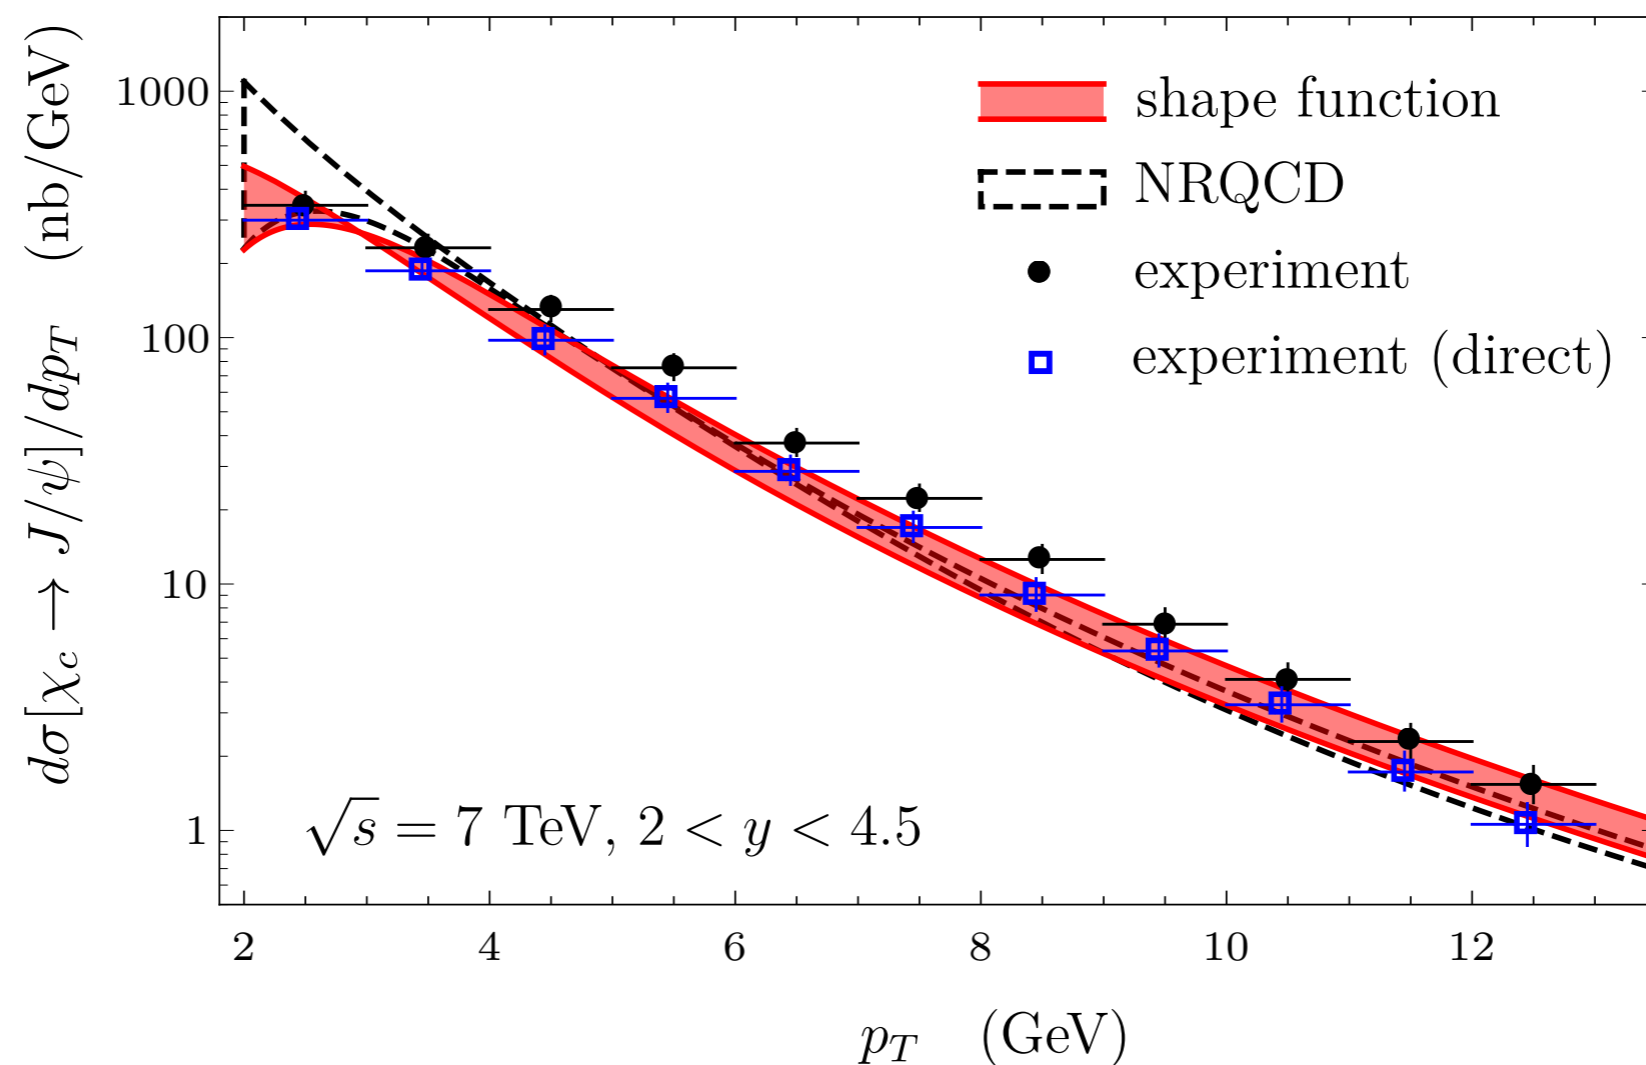

Cross Section Measurements

- Small-p_T data available from
  LHCb measurements of $\sigma(J/\psi)$, $\sigma(\psi(2S))$, $\sigma(\Upsilon)$
  LHCb measurements of $\sigma(\chi_c)/\sigma(J/\psi)$, $\sigma(\chi_b)/\sigma(\Upsilon)$

$\sigma(\chi_c)$ and $\sigma(\chi_b)$ can be obtained from their products.

$\times$ $= \sigma(\chi_c)$

$\times$ $= \sigma(\chi_b)$

14

χ_c Cross Sections
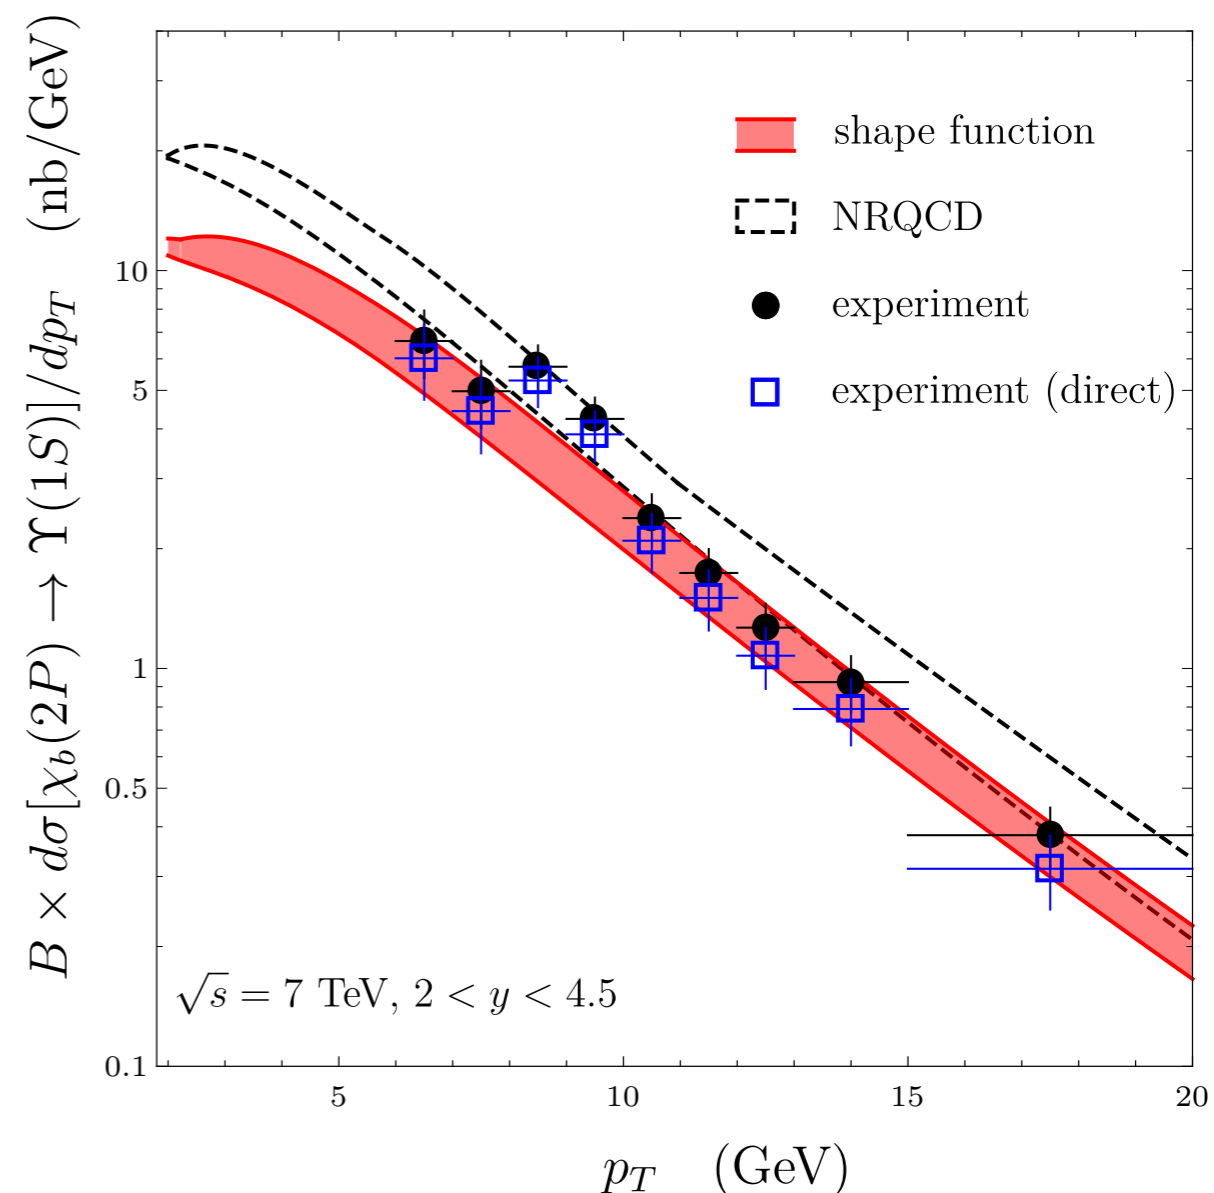

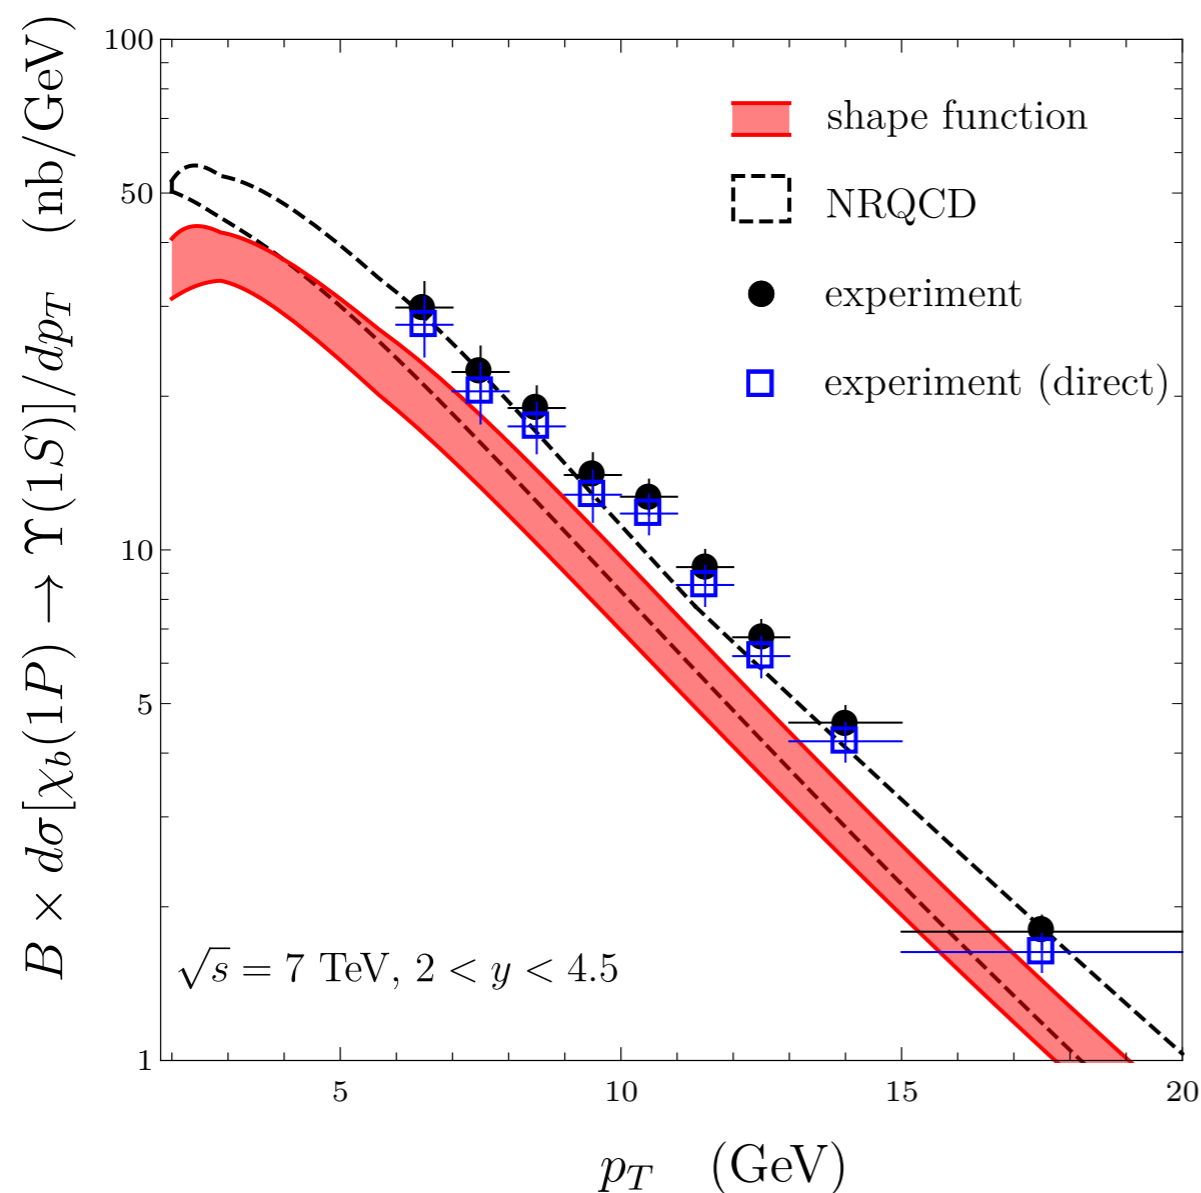

- *P*-wave charmonium cross sections

Experiment from LHCb, EPJC71 (2011) 1645, PLB718 (2012) 431
**feeddown subtraction using LHCb, EPJC 72 (2012) 2100**

χ_b Cross Sections

- *P*-wave bottomonium cross sections

Experiment from LHCb, EPJC74 (2014) 3092, JHEP11 (2015) 103
**feeddown subtraction using LHCb, JHEP11 (2015) 103**

Going to lower p_T

- If we were to extrapolate this down to even smaller p_T…

LHCb, **EPJC74 (2014) 3092**

χ_b Cross Sections

- *P*-wave bottomonium cross sections

extrapolation of LHCb, EPJC74 (2014) 3092

- A recent data-driven study suggests similar behaviors of small-p_T cross sections. **Boyd, Strickland, Thapa, PRD108, 094024 (2023)**

- Although direct measurements are not available, knowledge of low-p_T behavior is important for treatment of feeddown in Υ production

Summary

- NRQCD involves *mixing* induced by *soft gluon emission*.
Soft momentum can be important near boundaries of phase space.

- *Kinematical effects from soft momenta* can be **resummed** by shape function formalism, but this depends on unknown nonperturbative functions. Phenomenological application was *very limited*.

- This work revealed relation between ***shape function formalism*** and ***renormalization in NRQCD***. This severely constrains model dependence and ***restores predictability*** to standard NRQCD level.

- Inclusion of nonperturbative kinematical corrections ***soften the small-p_T behavior*** of χ_c, χ_b cross sections, potentially improving theory description of p_T-dependent χ_c, χ_b cross sections.

- Shape function allows reorganization of threshold logarithms into $g \to gg$ and $Q\bar{Q} \to Q\bar{Q}g$, which can help simplify resummation needed for quarkonium production at very large ***p_T***: *work in progress*
