

# Quick report on CHIMERA 2022 run

Kacper Bilko and Ruben Garcia Alia on behalf of the entire CHIMERA team!

Core test team during 5-day 2022 CHIMERA run: E. Johnson, K. Bilko, N. Emriskova, A. Waets, A. Coronetti

Many thanks to the PS/LIER/LINIAC3 operation, RP, CHARM and IRRAD teams for the support!

01/12/2022

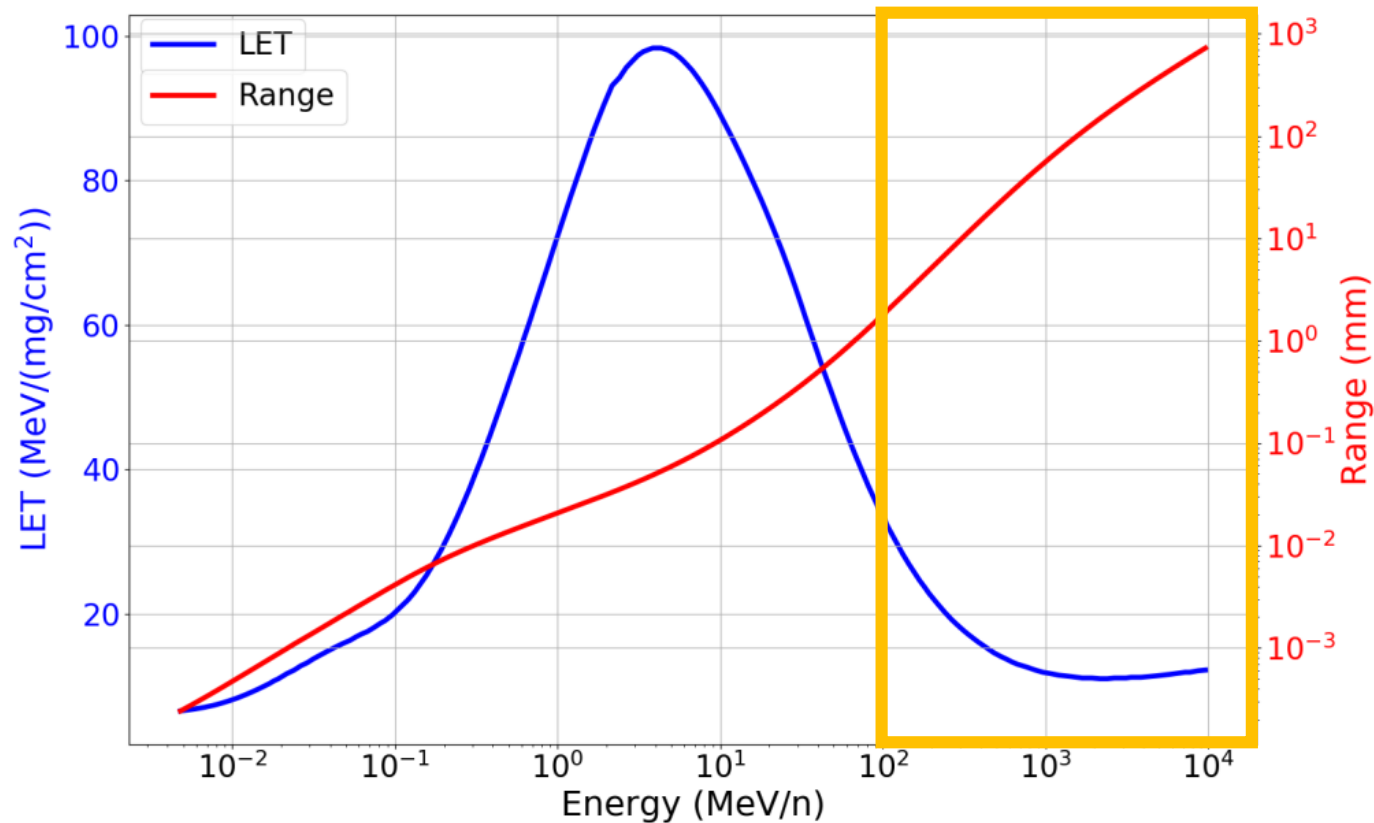

# CHIMERA high-level objectives and schedule

- To provide high-energy (>100 MeV/u) **heavy-ion beams** for radiation effects testing of electronics, for **accelerator and space applications**, and with the support of the **European Space Agency (ESA)** and European Commission,
- More specifically, **in the 2022 run**:
  - From an accelerator perspective: to provide **variable energy and intensity**, in a **controlled** manner,
  - From a beam instrumentation/radiation monitor perspective: to accurately measure the beam energy/LET and flux at the Device Under Test (DUT) location,
- **2022 experimental schedule**:
  - Several parallel MDs since ion setup in PS, with the beam propagated until the F61 East Area dump
  - Two dedicated Wednesday MDs with the beam propagated down to T8,
  - 5-day run from 23/28-11, including external users from ESA (2 days),
    - 23-24.11 – Beam Characterization by R2E,
    - 25-26.11 – External user tests (ESA),
    - 27-28.11 – R2E tests and MD activities (e.g. quad scan)

Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
20	21	22	23	24	25	26
			R2E beam characterization	R2E beam characterization	ESA	ESA R2E tests
27	28	29	30	1	2	3
R2E tests, Quad. Scan, New energies,						

# East Area ions for radiation effects testing

Key concept: by varying the lead beam energy, a reasonably broad LET range can be explored, with relatively large penetration capacity in matter (which is an important asset for modern microelectronics components and boards)

Desired heavy-ion beam properties:

- Few energies to provide different beams with the LET variation,
- Long spill, with the relatively uniform time profile (no peaks),
- Large beam at the DUT (FWHM of few cm),

# Heavy-ion beam: energy variation

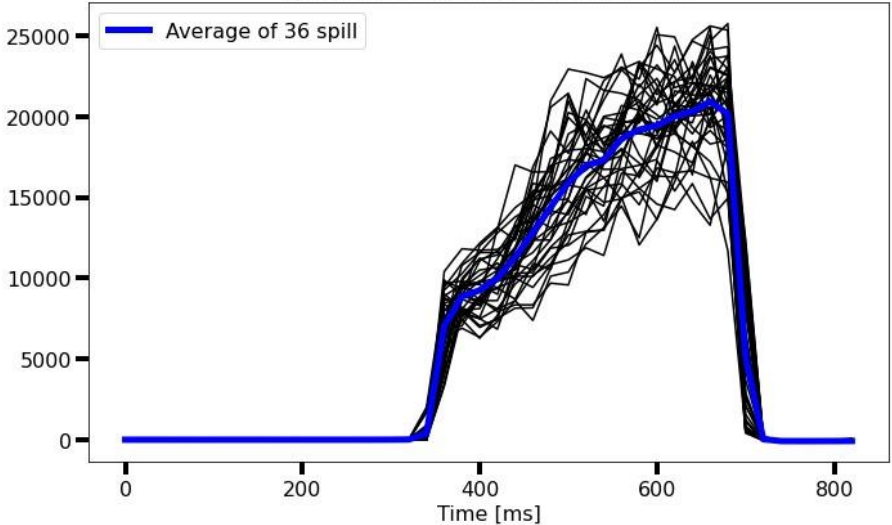

- Three PS energies selected for CHIMERA 2022 run, with the main objective of yielding a relatively large LET range ( $\sim 13\text{-}25 \text{ MeVcm}^2/\text{mg}$ ) at the device-under-test location
- Significant energy degradation along the line, mainly due to the long (several 10s of meters) sections in air, as demonstrated via a dedicated FLUKA simulations,
- Extracted PS energies: **1000MeV/u**, **750MeV/u**, **650MeV/u**,

# Heavy-ion beam: spill time profile

XION CPS.USER.MD5  
 from 2022-11-26 08:00:00.000 UTC  
 to 2022-11-26 10:00:00.000 UTC

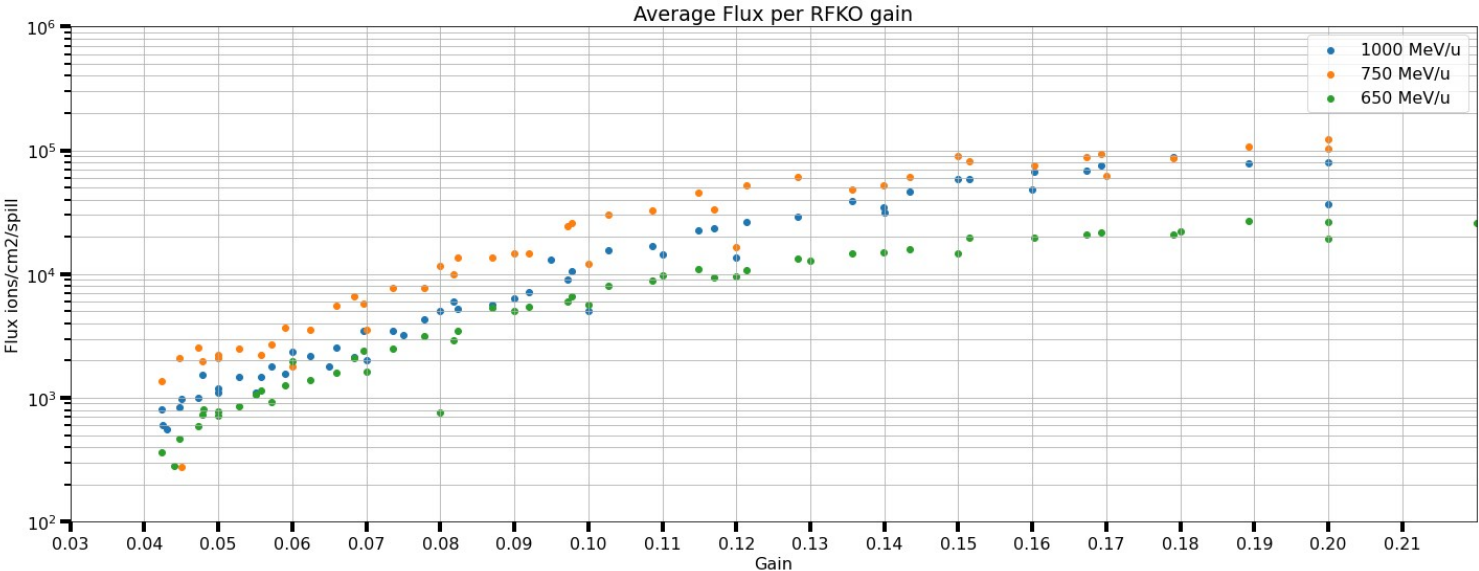

Run 5

Spill waterfall East Area  
 Most recent acquisition: 21h28m34s

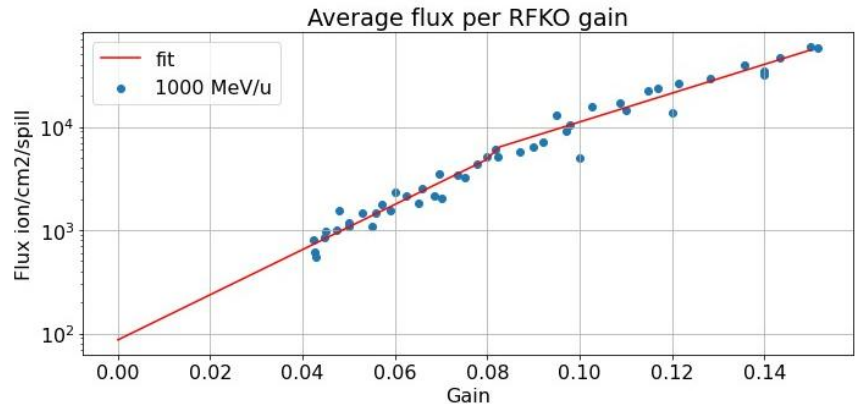

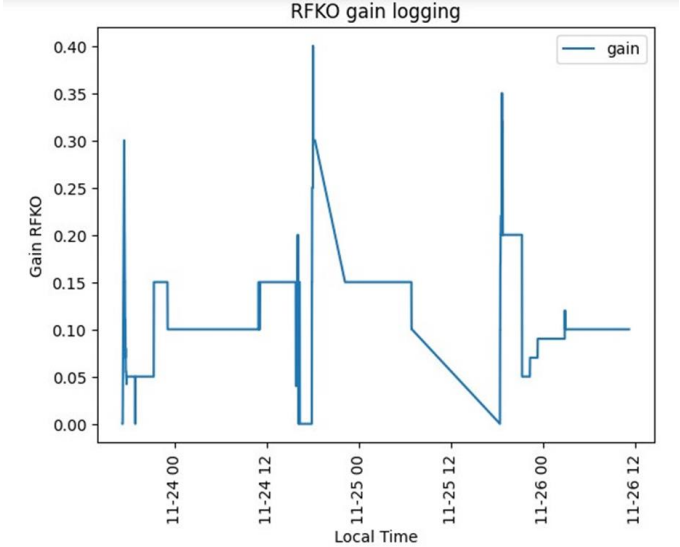

- Measured with a variety of instruments
- Overall, the spill time structure is long and uniform enough for radiation effects testing
- 130 kHz (7.7ms) structure observed, coming from the TFB plates (extraction pulsing every three turns because of tune of machine and resonant frequency of TFB)

# Heavy-ion beam: intensity control via the gain of RFKO

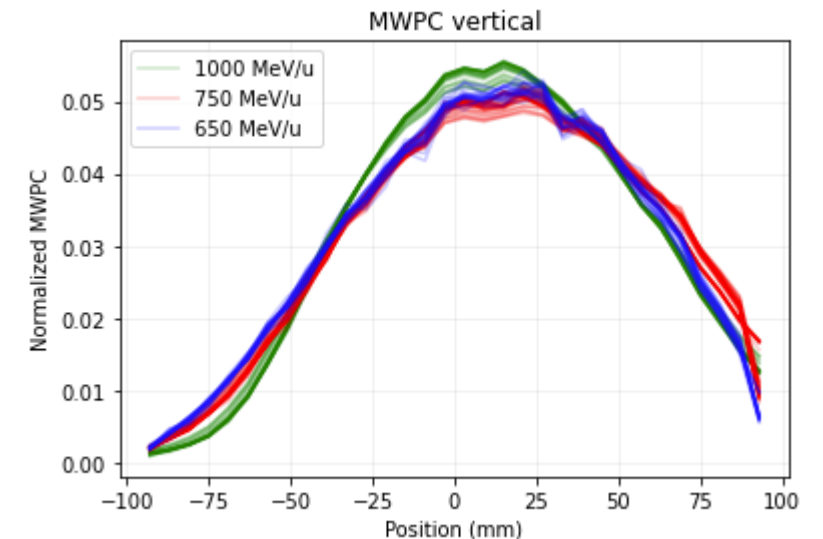

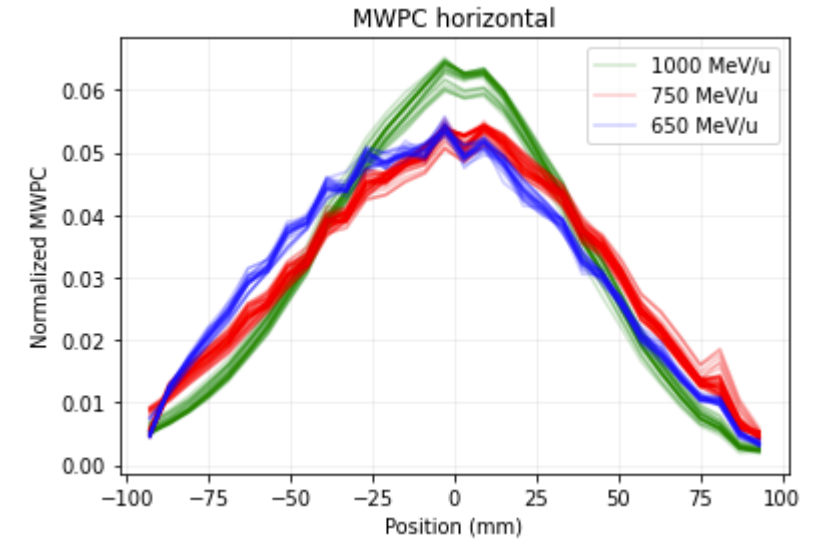

- Radio Frequency Knockout (RFKO),
- Well behaved and reproducible relationship between gain and intensity/flux
- Through this technique, the beam flux could be easily selected within a range of almost two orders of magnitude,

# Heavy-ion beam: spatial profile at testing location

- Based on the **Multi-Wire Proportional Chamber (MWPC)**,
- Operated mostly at **high voltage** (1.8 kV) to increase the sensitivity, as opposed to the nominal 0.1 kV,
- Adequately **covering intensity range used in the tests**,
- Relatively large beam: **FWHM ~10 cm**,
- Profile seems independent of beam intensity,
- To be analyzed:
  - Stability of beam profile throughout different runs,
- Possible option for the future: further de-focus the beam and apply rectangular collimation in the center, for homogeneous, rectangular beam

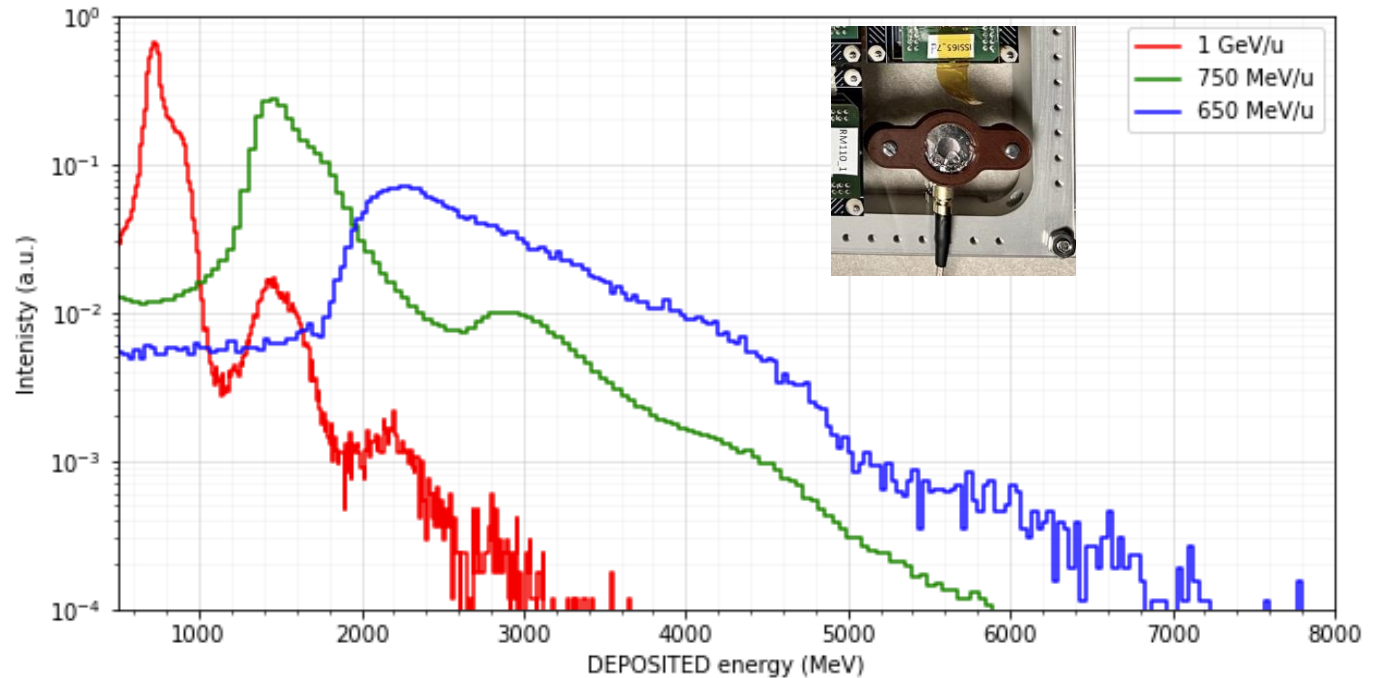

# R2E Beam Characterization: Si diode and SRAMs

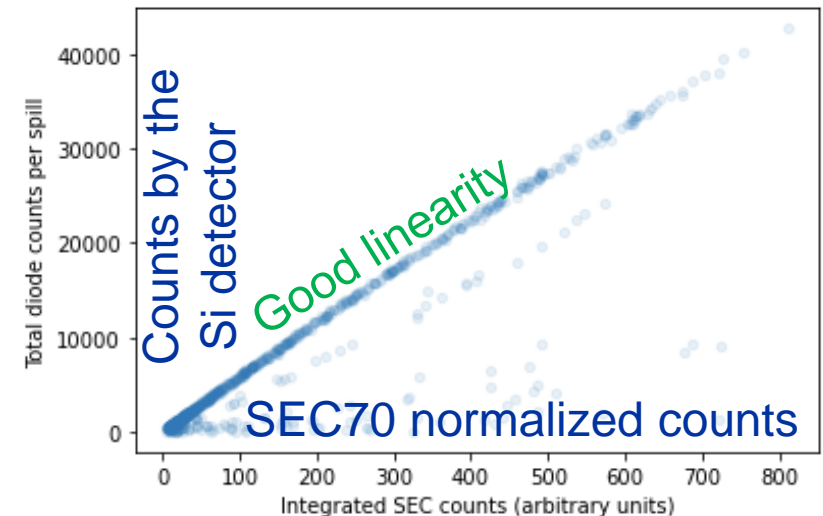

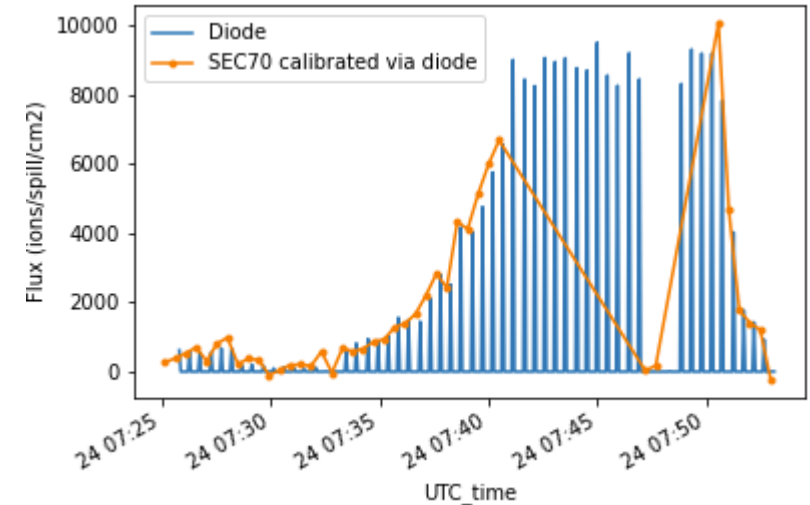

# Diode as beam diagnostics: event-by-event energy deposition,

- The diode provides an extremely powerful beam diagnostics tool, as it counts ion by ion, and provide the additional information of the energy deposited by each ion (in 300 $\mu\text{m}$  of silicon)
- The measured energy deposition spectra can be benchmarked against **FLUKA simulations** to retrieve beam energy and the corresponding LET,
- Counts ion by ion, therefore can be exploited for the intensity monitoring,

# Diode as beam diagnostics: flux monitor

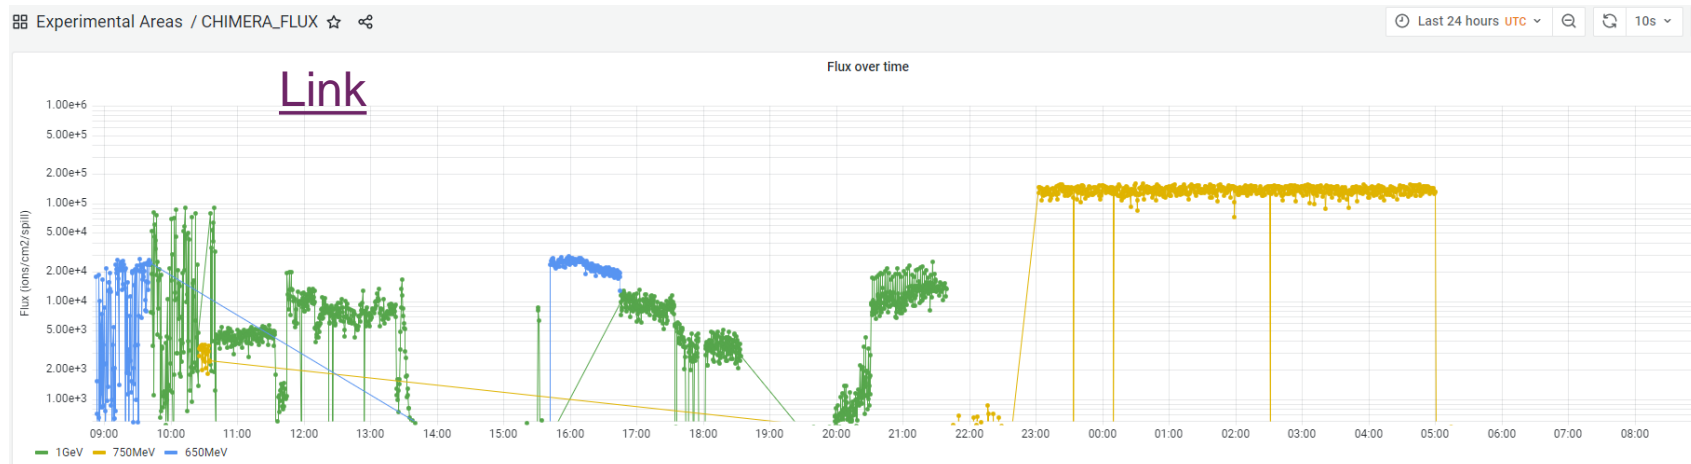

- As the diode measures deposition events from single ions, one can use it as a flux monitor, simply by taking the counts corresponding to the primary beam, and dividing by its sensitive surface
- For a given beam shape, the flux at the center of the beam should be proportional to its intensity. Therefore, one can use the diode to obtain a conversion factor between intensity (e.g. as measured by SEC70) and flux,
- This was applied during the online analysis (dashboard) and, when benchmarked against the SRAM memories,

# Beam instrumentation: flux estimate based on SEC70 and diode

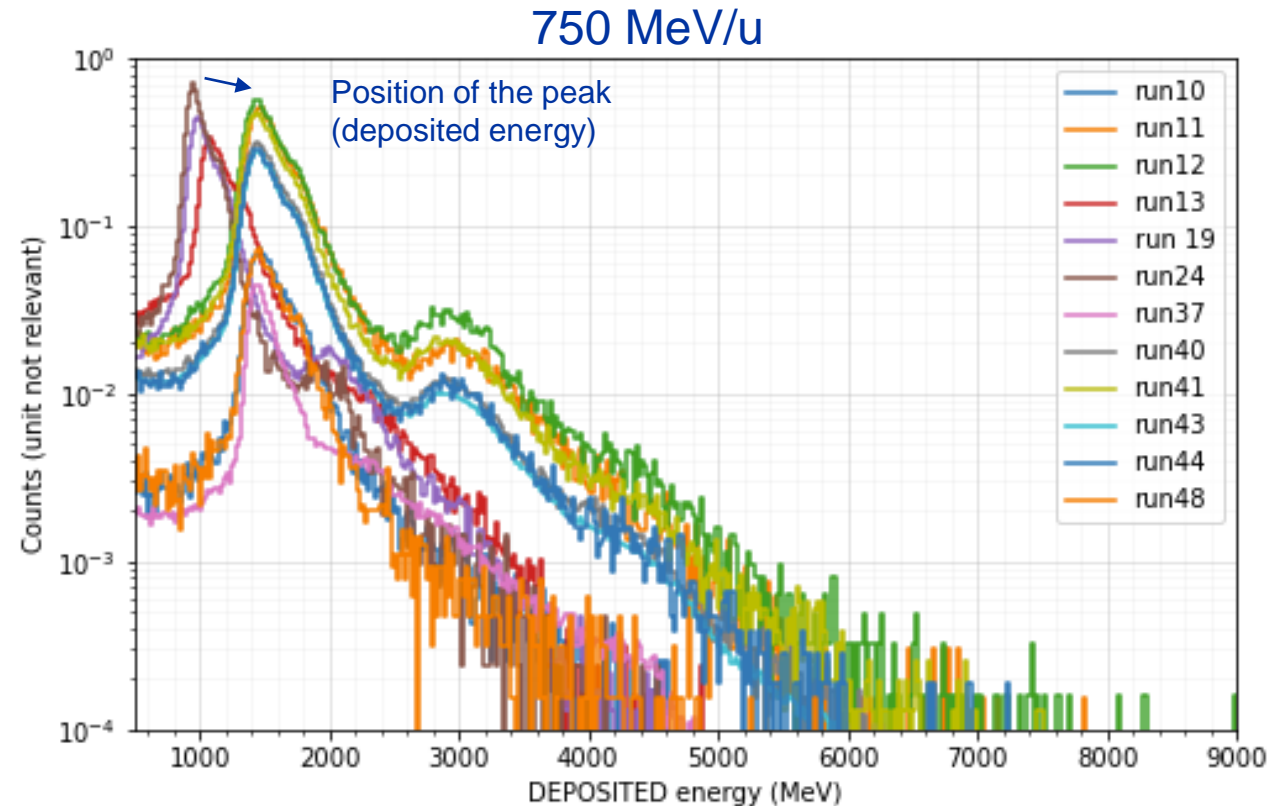

Online [dashboard](#) with the implemented R2E Beam Characterization – very useful and necessary for the users, as their test relied on “real time” flux measurements

Flux at the DUT as measured by SEC70, calibrated with the Si diode

# Open point: mysterious energy change (preliminary!)

- Over the CHIMERA run, as measured by the Si diode, the energy at the DUT (in CHARM) varied,
- This was observed for all three primary beam energies (1GeV/u, 750MeV/u, 650MeV/u),
- For each of the primary beam energy (PS), 2 beam energies at DUT were observed,
- Investigations are ongoing...
- Maybe additional material budget being put in and out of the line?

# Conclusions

- Very **successful test campaign** – a lot of data collected, waiting to be analyzed in detail
  - Data analysis and reporting will be as important as test preparation and execution,
- **No blocking issues with the PS** (e.g. frequent POPS trips) **and with the relevant Beam Instrumentation** (SECs, XIONs, MWPC),
- Delivered heavy-ion beam:
  - Extracted beams of 3 primary energies: 1 GeV/u, 750 MeV/u, 650 MeV/u,
  - **Long spills** (~400 ms), with the **relatively constant intensity** over spills (neglecting 130 kHz structure),
  - Thanks to the intensity control via RFKO, seems that **spill time and spatial profiles were independent of the intensity** itself (not the case with the other tested slow extraction techniques),
  - **Very good spatial profile**: at the test location (CHARM) beam had approximately 10 cm FWHM,
  - Open point: What may have changed the energy of the beam throughout the different runs?
    - Additional material budget being put in and out of the line?

# Intensity knob: gain of RFKO

Slow extraction intensity control through Radio Frequency-Knockout (RFKO)

## Normal slow extraction

## RFKO slow extraction

**Gain** setting used to increase/decrease the intensity of the extracted beam

## Coarse gain scan
