

Large Charge 't Hooft Limit

Shota Komatsu

Based on [arXiv: 2306.00929](https://arxiv.org/abs/2306.00929) with **Joao Caetano** (CERN), **Yifan Wang** (NYU)
& works / discussion in progress + **Jingxiang Wu** (Oxford) (1/16-BPS)
+ **Nicola Dondi** (Bern) (“dual” description)

Let's start with some beautiful formula

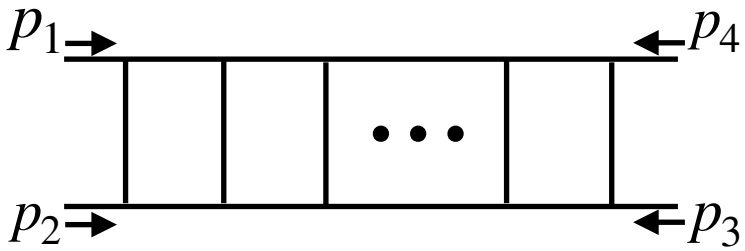

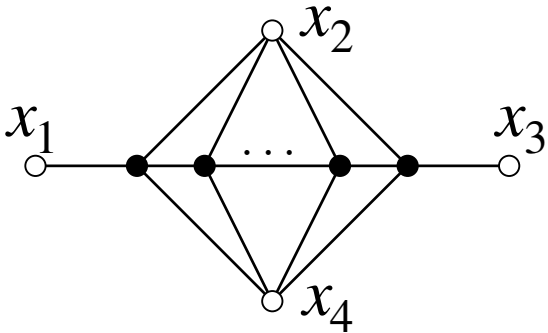

Resummation of off-shell massless ladders

[Broadhurst, Davydychev '10]

Resummation of off-shell massless ladders

[Broadhurst, Davydychev '10]

$$\sum_n \lambda^n$$

$$= \sum_n \lambda^n$$

$x_{i,i+1} = p_i$

Resummation of off-shell massless ladders

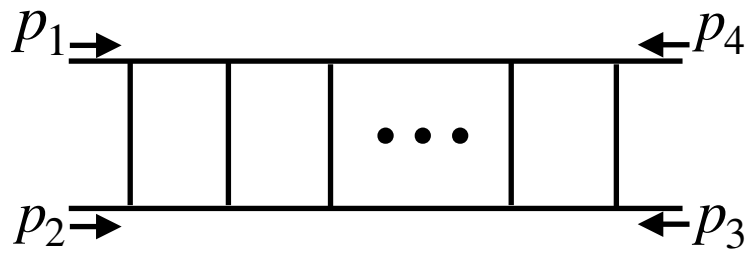

[Broadhurst, Davydychev '10]

$$\begin{aligned}
 & \sum_n \lambda^n \quad \begin{array}{c} \xrightarrow{p_1} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \xleftarrow{p_4} \\ \xrightarrow{p_2} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \xleftarrow{p_3} \end{array} \\
 &= \sum_n \lambda^n \quad \begin{array}{c} \circ x_2 \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \quad \dots \quad \bullet \quad \bullet \\ \diagdown \quad \diagup \\ \circ x_4 \end{array} \quad \begin{array}{c} \circ x_1 \text{---} \bullet \text{---} \bullet \text{---} \dots \text{---} \bullet \text{---} \bullet \text{---} \circ x_3 \end{array} \\
 &= \sum_n \lambda^n F^{(n)}(z, \bar{z}) \quad \begin{array}{c} z\bar{z} = \frac{x_{12}^2 x_{34}^2}{x_{13}^2 x_{24}^2} \end{array}
 \end{aligned}$$

$$F^{(n)}(z, \bar{z}) = \sum_{r=0}^k \frac{(-1)^r (2k-r)!}{k!(k-r)!r!} (\log(z\bar{z}))^r (\text{Li}_{2k-r}(z) - \text{Li}_{2k-r}(\bar{z}))$$

Resummation of off-shell massless ladders

[Broadhurst, Davydychev '10]

$$\sum_n \lambda^n$$

The diagram shows a ladder structure with four external momenta: p_1 (top left, right arrow), p_2 (bottom left, right arrow), p_3 (bottom right, left arrow), and p_4 (top right, left arrow). The ladder consists of a series of vertical rungs connected by horizontal lines. The number of rungs is denoted by n . Ellipses in the middle of the ladder indicate that there are more rungs than shown.

$$\lambda \rightarrow \infty \sim e^{-\sqrt{\lambda}}$$

cf. [Arkani-Hamed, Henn, Trnka '21]

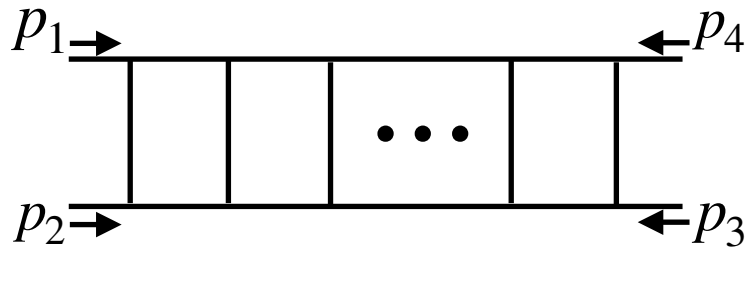

- Exponential suppression at strong coupling.
- Reminiscent of “stringy” behavior often seen in AdS/CFT

$$\langle W \rangle \stackrel{\lambda \rightarrow \infty}{\sim} e^{-\sqrt{\lambda} \text{Area}}$$

- A physical set up which leads to this resummation was not known.

Refinement

[Caetano, SK, Wang]

$$\sum_n \lambda^n$$

$$= \sum_m W(\varphi + 2\pi m) + W(2\pi - \varphi + 2\pi m)$$

$$W(x) = \frac{4xK_1 \left(\sqrt{\lambda(x^2 + \sigma^2)} \right)}{\sin x \sqrt{x^2 + \sigma^2}}$$

$$z = e^{\sigma + i\varphi}$$

Refinement

[Caetano, SK, Wang]

$$\sum_n$$

Massless loops

$$= \sum_m$$

Massive propagators

Why?

Punchline

- I will present a physical setup which naturally explains all these features.
- Large charge 't Hooft limit of $\mathcal{N} = 4$ super Yang-Mills
 - Far from the planar limit: SU(2) gauge group
 - Large number of particles
 - cf. Talk by Korchemsky
- The limit is *surprisingly rich* and exhibits *surprising similarity* with the planar limit.

Systems with large # of d.o.f

- Systems with large # of d.o.f often exhibit emergent phenomena.
- Two ways to introduce large # of d.o.f.
 1. Consider a **family of theories** (parametrized by “ N_c ”) and take $N_c \rightarrow \infty$.
 2. Consider a **state in a given theory** in which a large number of particles are excited.
- The former is the large N_c limit. The latter is common in cond-mat.

Large # of particles

For g and N small:
perturbation around free system

Effective interaction strength

$$\lambda_{\text{eff}} \sim gN$$

Large # of particles

$$\lambda_{\text{eff}} \sim g N$$

- Even if the fundamental interaction is weak ($g \ll 1$), the sector with a large # of particles can be strongly coupled.
- Suggests a **double scaling limit**, λ_{eff} : fixed, and $N \rightarrow \infty$.
- Formally this looks like a 't Hooft limit.....
- Is there any similarity with the standard 't Hooft limit.....?

“Duality”

[Polchinski, Silverstein '12]

- When viewed from fundamental strings, this is a **standard large N limit of 2d theory**.
- When viewed from NS5, this is a **large density state in 6d**.
- It suggests that the large charge and the large N_c can be sometimes dual descriptions of the same system.
- There is also a diagrammatic understanding based on **open-closed-open** triality.

[Gopakumar, unpublished], [Gopakumar, Mazenc '22]
[Goel, Verlinde '21], [WIP]

Large # of particles

- Relevant in various physically interesting set ups.

Cond-mat

- Large chemical potential, high density

High energy (ph)

- Amplitudes with many legs
- multi-particle production

High energy (th)

- Large charge state in CFT

Set up: $\mathcal{N} = 4$ SYM at large charge

- 4d $\mathcal{N} = 4$ SYM with $SU(2)$ gauge group.
- 1/2 BPS operator $\text{tr}(\phi^J)$ with large R-charge J and take cf. Talk by Korchemsky
 $J \rightarrow \infty$ with fixed $\lambda_J = g_{\text{YM}}^2 J$.
[Bourget, Rodriguez-Gomez, Russo'18]
- Study near BPS spectrum and correlation functions (heavy-heavy-light-light etc) in this limit.

Outline

1. Intro / motivation
- 2. Large charge limit vs large charge 't Hooft limit**
3. Results
4. Conclusion and future directions

Physics of large charge limit in CFT_d

[Alvarez-Gaume, Cuomo, Dondi, Giombi, Hellerman, Kalogerakis, Loukas, Monin, Orlando, Pirtskhalava, Rattazzi, Reffert, Sannino, Watanabe...]

- $\langle \mathcal{O}_J \bar{\mathcal{O}}_J \rangle$ at large charge \leftrightarrow large charge state on $R_t \times S_L^{d-1}$

\mathcal{O}_J : minimal dim op. for a given charge J

- $E_{\text{state}} = \frac{\Delta_{\text{min}}}{L} \rightarrow \epsilon_{\text{state}} = \frac{\Delta_{\text{min}}}{L^d}, \quad j_{\text{min}} = \frac{J}{L^{d-1}}$

- Large charge limit: $J \rightarrow \infty, L \rightarrow \infty$ with j_{min} finite.

- Lowest energy state in flat space with finite charge density.

Physics of large charge limit in CFT_d

$$\epsilon_{\text{state}} = \frac{\Delta_{\text{min}}}{L^d}, \quad j_{\text{min}} = \frac{J}{L^{d-1}}$$

- Generic (nonsupersymmetric) CFT_d : $j_{\text{state}} \sim \epsilon_{\text{state}} \sim O(1)$

$$\Delta \stackrel{J \rightarrow \infty}{\sim} J^{\frac{d}{d-1}}$$

[Alvarez-Gaume, Cuomo, Dondi, Giombi, Hellerman, Kalogerakis, Loukas, Monin, Orlando, Pirtskhalava, Rattazzi, Reffert, Sannino, Watanabe....]

- CFT with a moduli space of vacua: $j_{\text{state}} \sim O(1)$, $\epsilon_{\text{state}} = 0$.

e.g. BPS operator in SUSY CFT: $\Delta \propto J$

[Arias-Tamargo, Beccaria, Bourget, Hellerman, Maeda, Orlando, Rodriguez-Gomez, Reffert, Russo, Watanabe....]

Large charge limit from **path integral**

- Consider two point function of charged scalars $O_J = \phi^J$
$$\int \mathcal{D}\phi \exp \left(-S + \underline{J \log(\phi)\delta^d(x - x_1) + J \log(\bar{\phi})\delta^d(x - x_2)} \right)$$
- $J \rightarrow \infty$: path integral dominated by a saddle point
- In theories with coupling constant g_{YM} : $\langle \phi \rangle \sim g_{\text{YM}} \sqrt{J}$

Large charge limit from path integral

- Consider two point function of charged scalars $O_J = \phi^J$
$$\int \mathcal{D}\phi \exp \left(-S + \underline{J \log(\phi)\delta^d(x - x_1) + J \log(\bar{\phi})\delta^d(x - x_2)} \right)$$
- $J \rightarrow \infty$: path integral dominated by a saddle point
- In theories with coupling constant g_{YM} : $\langle \phi \rangle \sim g_{\text{YM}} \sqrt{J}$
- In supersymmetric gauge theories, the theory is effectively on the Coulomb branch.
- Mass of BPS W-bosons: $m_W \sim g_{\text{YM}} \sqrt{J} \rightarrow \infty$ ($J \rightarrow \infty$)
- Derivative expansion of (Coulomb branch) EFT = $1/J$ expansion

$$\frac{1}{p^2 + m_W^2} = \frac{1}{m_W^2} - \frac{p^2}{m_W^4} + \dots \sim \frac{\#}{J} + \frac{\#p^2}{J^2} + \dots$$

Large charge 't Hooft limit

- Large charge limit + EFT : powerful, universal predictions
- **But** it is insensitive to physics of **massive (BPS) excitations**

- Alternative limit:

[Bourget, Rodriguez-Gomez, Russo'18]

$$J \rightarrow \infty \text{ with } \lambda_J = g_{\text{YM}}^2 J \text{ fixed.}$$

- $m_W \sim \sqrt{\lambda_J}$ is finite. They contribute to obs even at $J \rightarrow \infty$.
- Results in the literature so far: supersymmetric (BPS) observables.
- **Our work**: non-supersymmetric (near BPS) observables.

Outline

1. Intro / motivation
2. Large charge limit vs large charge 't Hooft limit
- 3. Results**
4. Conclusion and future directions

Heavy-heavy-(light)ⁿ correlators

- Consider higher-point functions (HHLLLLL....)

$$\langle O_J(0)O_{i_1}(x_1)\dots O_{i_n}(x_n)O_J(\infty) \rangle = \langle J | O_{i_1}(x_1)\dots O_{i_n}(x_n) | J \rangle$$

- **Examples:** light BPS $\text{tr}((Y^I \phi_I)^\ell)$, Konishi $K \sim \text{tr}(\phi^I \phi_I)$

- Large charge 't Hooft limit:

$$\langle J | O_{i_1}(x_1)\dots O_{i_n}(x_n) | J \rangle \rightarrow \langle O_{i_1}(x_1)\dots O_{i_n}(x_n) \rangle_{\text{large charge bkd}} \quad \langle \phi \rangle \neq 0$$

- Basic building block: propagator in the background

$$\langle \phi(x)\phi(y) \rangle_{\text{bkd}}$$

Propagator in the background

$$\langle \phi(x)\phi(y) \rangle_{\text{bkd}}$$

- Satisfies a (complicated-looking) differential equation.

$$\mathcal{D} \langle \phi(x)\phi(y) \rangle_{\text{bkd}} = \delta^4(x - y)$$

- Surprisingly, the solution is given by a resummation of ladders!

[Giombi, Hyman '20]

$$\langle \phi\phi \rangle_{\text{bkd}} \sim \sum \text{[Ladder Diagrams]} = \sum_k \lambda_J^k F^{(k)}(z, \bar{z})$$

Physical explanation of $e^{-\sqrt{\lambda_J}}$

Large charge state on a cylinder

$\lambda_J \rightarrow \infty$

Coulomb branch in flat space

\rightarrow

Propagation of massive W-boson

Physical explanation of $e^{-\sqrt{\lambda_J}}$

$$W(x) = \frac{xK_1(\sqrt{\lambda_J}\sqrt{x^2 + \sigma^2})}{\sin x\sqrt{x^2 + \sigma^2}}$$

$$= \frac{(1-z)(1-\bar{z})}{\sqrt{z\bar{z}}} \sum_{n=0}^{\infty} W(\varphi + 2\pi n) + W(2\pi - \varphi + 2\pi n)$$

Worldline instantons
wrapping cylinder

Some other nice results

Result for Konishi 3pt

- Using the propagator, we computed the 3pt function $\langle \mathcal{O}_J K \mathcal{O}_J \rangle$
($K \sim \text{tr}(\phi^I \phi_I)$)

$$C_{KJJ} = -8\lambda + 4\sqrt{\lambda} \int_0^\infty dw \frac{4\sqrt{\lambda}w - J_1(8\sqrt{\lambda}w)}{\sinh^2(w)}$$

- Weak coupling expansion: **finite radius of convergence** $|\lambda| < 1/16$.
“magnon” becoming massless, tachyonic instability $\sqrt{1 + 16\lambda}$
- Strong coupling expansion:

$$C_{KJJ} = \frac{\lambda}{2\pi^2} \left(\gamma_E + \log \frac{\lambda}{4\pi^2} \right) - \frac{2\lambda}{\pi^2} \sum_{n=1}^{\infty} \left(K_1(2n\sqrt{\lambda}) + K_0(2n\sqrt{\lambda}) \right)$$

- Similar expressions seen in the planar limit (cusp anomalous dim etc)**

Spectrum around large charge operator

- The spectrum of excitations around the large charge operator.

$$\mathcal{O} = \text{tr}(\phi^J) + \text{corrections}$$

- Result:

(Gauge invariant) combinations of “magnons” with energy

$$E_{\text{magnon}} = \sqrt{1 + 16\lambda_J}$$

Spectrum around large charge operator

- The spectrum of excitations around the large charge operator.

$$\mathcal{O} = \text{tr}(\phi^J) + \text{corrections}$$

- Result:

(Gauge invariant) combinations of “magnons” with energy

$$E_{\text{magnon}} = \sqrt{1 + 16\lambda_J}$$

- Planar limit:

(Gauge invariant) combinations of magnons with momentum p

$$E_{\text{magnon}} = \sqrt{1 + 16\lambda_J \sin^2 p/2}$$

- In both limits, the spectrum is fully fixed by centrally-extended $\mathfrak{psu}(2|2)^2$ [Beisert '06]

Diagrammatic interpretation of “duality”

- Large charge limit and large N limit are sometimes dual. [Polchinski, Silverstein '12]
- **Q:** Is there a “planar” expansion at large charge?
- **A:** planar “dual graphs” (at least in some cases) [WIP + Dondi]

- Studied before in the conventional large N limit: “open-closed-open triality”

Outline

1. Intro / motivation
2. Large charge limit vs large charge 't Hooft limit
3. Results
4. Conclusion and future directions

Conclusion

- Large charge 't Hooft limit provides an interesting solvable corner of $\mathcal{N} = 4$ SYM.
Many more to explore!
 - Underlying centrally extended symmetry.
 - Various observables can be computed exactly as a function of λ_J .
Integrated correlators in terms of $J \times J$ matrix integral.
-
- Other limits? Large spin 't Hooft limit $g_{\text{YM}}^2 \log S$
Effective description in terms of 2d YM. [Alday, Maldacena 08]
Similarity with BFKL limit.
It's likely that the limit can be studied also in QCD(?)
 - Holography for large density, large # of particles, large # of legs?

 - Holography for large density, large # of particles, large # of legs?
 - We might not need large N for AdS/CFT. AdS/CFT for collider?

Back up slides

Centrally-extended $\mathfrak{psu}(2|2)^2$

- Consider a large charge BPS op and perturb it:

$$|Z\dots Z\chi Z\dots Z\chi Z\dots Z\rangle$$

- Subgroup of superconformal symmetry preserved by large charge 1/2 BPS state $\rightarrow \mathfrak{psu}(2|2)^2$
- **Excitations** are classified by irreps of $\mathfrak{psu}(2|2)^2$.
- But (as expected) it is not powerful enough to constrain the dynamics. No g_{YM} dependence.
- The actual symmetry is larger: **centrally-extended $\mathfrak{psu}(2|2)^2$**

Centrally-extended $\mathfrak{psu}(2|2)^2$

- In general superconformal algebra, $\{Q, Q\} = 0$.
- This is true when acting on gauge inv states. **But not true for individual fields.**

$$\{Q, Q\}\chi \sim [Z, \chi]$$

- Maximally centrally extended $\mathfrak{psu}(2|2)^2$

$$\{Q, S\} \sim D - \hat{J}$$

$$\{Q^a_\alpha, Q^b_\beta\} = \epsilon^{ab}\epsilon_{\alpha\beta} \mathbf{P}, \quad \{S^\alpha_a, S^\beta_b\} = \epsilon_{ab}\epsilon^{\alpha\beta} \mathbf{K}$$

$$\mathbf{P} \cdot \chi \equiv [Z, \chi], \quad \mathbf{K} \cdot \chi \equiv [Z^{-1}, \chi]$$

Centrally-extended $\mathfrak{psu}(2|2)^2$

$$\{Q^a_\alpha, Q^b_\beta\} = \epsilon^{ab}\epsilon_{\alpha\beta} P, \quad \{S^\alpha_a, S^\beta_b\} = \epsilon_{ab}\epsilon^{\alpha\beta} K$$

$$P \cdot \chi \equiv [Z, \chi], \quad K \cdot \chi \equiv [Z^{-1}, \chi]$$

- In the **planar limit**, P and K can be identified with translations on spin chain.
- In the **large charge 't Hooft limit**, the action of P and K are determined by VEV of Z induced by the charge.

$$\langle Z \rangle = \begin{pmatrix} \frac{g_{\text{YM}}\sqrt{J}}{2\pi} e^{i\varphi} & 0 \\ 0 & -\frac{g_{\text{YM}}\sqrt{J}}{2\pi} e^{i\varphi} \end{pmatrix}$$

- $\{Q, Q\} m^\pm \sim \pm 2\lambda m^\pm, \{Q, Q\} m^0 = 0.$

$$\chi = \begin{pmatrix} m^0 & m^+ \\ m^- & -m^0 \end{pmatrix}$$

Centrally-extended $\mathfrak{psu}(2|2)^2$

$$\{Q^a_\alpha, Q^b_\beta\} = \epsilon^{ab}\epsilon_{\alpha\beta} P, \quad \{S^\alpha_a, S^\beta_b\} = \epsilon_{ab}\epsilon^{\alpha\beta} K$$

$$\{Q, S\} \sim D - \hat{J}$$

- By requiring that the centrally-extended algebra closes on $|Z\dots m^\pm \dots Z\rangle$ (BPS rep)

$$(D - \hat{J}) |Z\dots m^\pm \dots Z\rangle = \sqrt{1 + 16\lambda} |Z\dots m^\pm \dots Z\rangle$$

$$(D - \hat{J}) |Z\dots m^0 \dots Z\rangle = |Z\dots m^0 \dots Z\rangle$$

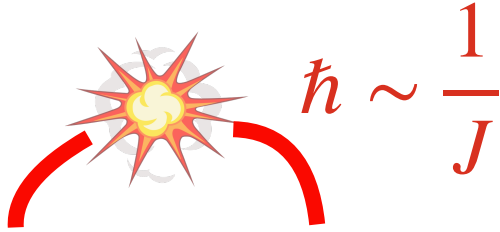

- To construct a gauge inv state, we require $\# m^+ = \# m^-$

e.g. $|Z\dots Z m^- m^- m^0 Z\dots Z m^+ m^+ Z\dots Z\rangle$

$$\text{Energy} = \sum \text{individual energies} \quad \Delta - J = 1 + 4\sqrt{1 + 16\lambda}$$

(interactions $\sim 1/J$)

Spectrum at $1/J$

The diagram shows a chain of sites represented by 'Z' characters. A central part of the chain contains three sites with magnon excitations: m^- , m^- , and m^0 . To the right, there are two sites with m^+ excitations. A red sun-like symbol with rays is positioned above the chain, with two red curved lines connecting it to the two m^+ sites. To the right of the sun symbol, the text $\hbar \sim \frac{1}{J}$ is written in red.

$$|Z\dots Z m^- m^- m^0 Z\dots Z m^+ Z\dots Z m^+ Z\dots Z\rangle$$

- At $1/J$, there is 2-body interaction among excitations (“magnons”).
- Since we are not in the planar limit, the interaction is “all-to-all”.
- Centrally-extended $\mathfrak{psu}(2|2)$ is still powerful: It determines the interaction Hamiltonian up to a few overall coefficient.

Result for Konishi 3pt
