Focus points

- 1 - Reheating after inflation
- 2 - Gravitational portals to DM and radiation
- 3 - Gravitational reheating and GWs constraints
- 4 - Gravitational portals to leptogenesis

1- Reheating after inflation

From (P)reheating Effects of the Kähler Moduli Inflation I Model, Islam Khan, Aaron C. Vincent and Guy Worthey, 2111.11050

Redshifted envelop and frequency of the oscillations depend on the shape of the potential near the minimum

EOM: $\ddot{\phi}(t) + 3H\dot{\phi}(t) + \Gamma\dot{\phi}(t) + V'(\phi(t)) = 0$

Couplings of the inflaton with the other fields induce transfer of energy during the oscillations : (p)reheating !

$$w = \frac{P_\phi}{\rho_\phi} = \frac{\frac{1}{2}\langle\dot{\phi}^2\rangle - \langle V(\phi)\rangle}{\frac{1}{2}\langle\dot{\phi}^2\rangle + \langle V(\phi)\rangle} = \frac{k-2}{k+2}$$

Perturbative processes

Inflaton sector can also handle non-thermal **Dark Matter (DM)** production through **perturbative processes**

→ From **inflaton background direct decay** to DM, see for example *Reheating and Post-inflationary Production of Dark Matter*, Garcia, Kaneta, Mambrini, Olive, **2004.08404**

→ From **inflaton portal**, in which the inflaton mediates between SM and DM sectors, see *The Inflaton Portal to Dark Matter*, Heurtier, **1707.08999**

→ From **inflaton scattering mediated by a (massive) particle**, see for example, *Gravitational Production of Dark Matter during Reheating*, Mambrini, Olive, **2102.06214**

2 - Gravitational portals to DM and radiation

→ Graviton portal arises from metric perturbation around its locally flat form

$$g_{\mu\nu} \simeq \eta_{\mu\nu} + 2h_{\mu\nu}/M_P$$

$$\mathcal{L}_{\text{min.}} = -\frac{1}{M_P} h_{\mu\nu} \left(T_h^{\mu\nu} + T_\phi^{\mu\nu} + T_X^{\mu\nu} \right)$$

→ Consider massless gravitons and from the stress-energy of spin 0, 1, ½ fields we can compute the amplitudes for the processes

Spin-2 Portal Dark Matter, Bernal, Dutra, Mambrini, Olive, Peloso, **1803.01866**

Gravitational Production of Dark Matter during Reheating, Mambrini, Olive, **2102.06214**

$$T_0^{\mu\nu} = \partial^\mu S \partial^\nu S - g^{\mu\nu} \left[\frac{1}{2} \partial^\alpha S \partial_\alpha S - V(S) \right],$$

$$T_{1/2}^{\mu\nu} = \frac{i}{4} \left[\bar{\chi} \gamma^\mu \overleftrightarrow{\partial}^\nu \chi + \bar{\chi} \gamma^\nu \overleftrightarrow{\partial}^\mu \chi \right] - g^{\mu\nu} \left[\frac{i}{2} \bar{\chi} \gamma^\alpha \overleftrightarrow{\partial}_\alpha \chi - m_\chi \bar{\chi} \chi \right],$$

$$T_1^{\mu\nu} = \frac{1}{2} \left[F_\alpha^\mu F^{\nu\alpha} + F_\alpha^\nu F^{\mu\alpha} - \frac{1}{2} g^{\mu\nu} F^{\alpha\beta} F_{\alpha\beta} \right]$$

The **natural generalization** of this minimal interaction is to introduce **non-minimal couplings** to gravity of the form :

$$\mathcal{L}_{\text{non-min.}} = -\frac{M_P^2}{2}\Omega^2\tilde{R} + \mathcal{L}_\phi + \mathcal{L}_h + \mathcal{L}_X \quad \text{with} \quad \Omega^2 \equiv 1 + \underbrace{\frac{\xi_\phi\phi^2}{M_P^2}}_{\text{inflaton}} + \underbrace{\frac{\xi_h h^2}{M_P^2}}_{\text{SM}} + \underbrace{\frac{\xi_X X^2}{M_P^2}}_{\text{DM}}$$

in the **Jordan frame**

$$g_{\mu\nu} = \Omega^2 \tilde{g}_{\mu\nu}$$

$$\mathcal{L}_{\text{non-min.}} = -\sigma_{hX}^\xi h^2 X^2 - \sigma_{\phi X}^\xi \phi^2 X^2 - \sigma_{\phi h}^\xi \phi^2 h^2$$

in the **Einstein frame**

This non-minimal couplings induce **leading-order interactions** in the small fields limit, involved in **radiation and DM production**.

Reheating and Dark Matter Freeze-in in the Higgs-R² Inflation Model, Aoki, Lee, Menkara, Yamashita, **2202.13063**

Gravitational Portals with Non-Minimal Couplings, SC, Mambrini, Olive, Shkerin, Verner, **2203.02004**

Gravitational portals can connect different sectors :

→ Thermal bath and DM through the FIMP scenario

→ Inflaton and DM to directly produce DM from the condensate

→ Inflaton and the thermal bath to initiate the reheating process

But inflaton scattering cannot reheat entirely ($\rho_\phi = \rho_{\text{Radiation}}$) in a quadratic potential ($\propto \phi^2$) as the radiation produced is more “redshifted” than the inflaton energy density

Gravitational portals in the early Universe, SC, Mambrini, Olive, Verner, 2112.15214

Figure 1 : Energy densities of *inflaton* (blue), *total radiation* (red), radiation from *inflaton decay* (orange), from *scattering mediated by graviton* (purple) and from *non-minimal coupling* (green), with $\xi_h = \xi = 2$

+

+

Figure 1 : Energy densities of *inflaton* (blue), *total radiation* (red), radiation from *inflaton decay* (orange), from scattering mediated by graviton (purple) and from *non-minimal coupling* (green), with $\xi_h = \xi = 2$

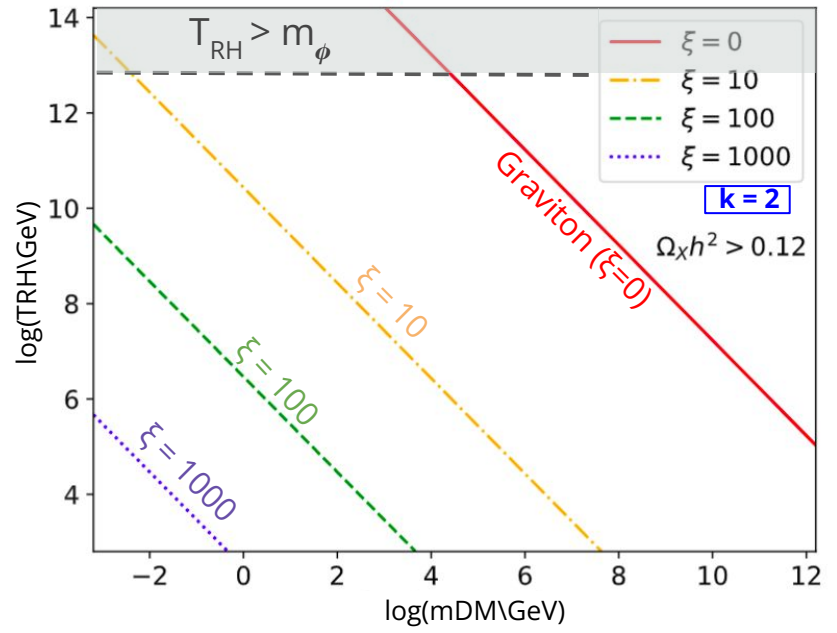

Figure 2 : Contours respecting $\Omega_\chi h^2 = 0.12$ for *spin 0 DM*, for different values of $\xi_h = \xi_x = \xi$. Both *minimal and non-minimal contributions* are added.

→ Non-minimal couplings alleviate difficulties to produce DM and radiation through gravitational portals

3 - Gravitational reheating and GWs constraints

→ Graviton exchange processes can be sufficient to reheat entirely, for sufficiently steep inflaton potential : $k > 9$

Gravitational Reheating, Haque, Maity, **2201.02348**

Inflationary Gravitational Leptogenesis, Co, Mambrini, Olive, **2205.01689**

$$\rho_\phi(a) \propto \left(\frac{a_{\text{end}}}{a}\right)^{\frac{6k}{k+2}} \quad \rho_R(a) \propto \left(\frac{a_{\text{end}}}{a}\right)^4$$

→ The requirement of large k can be relaxed if we add the non-minimal contribution to radiation production, (but still need $k > 4$).

Figure 3: Reheating temperature from gravitational portals as function of k , for different ξ_h

→ Primordial GWs re-entering the horizon during reheating, if inflaton redshifts faster than radiation, are enhanced.

→ GWs spectrum scales with the frequency as $\Omega_{\text{GW}}^0 h^2 \propto f^{k-4/k-1}$

→ The slope of this spectrum can probe the shape of the inflaton potential near the minimum

The largest enhancement is for the mode that re-enters the horizon right after inflation

Figure 4 : Primordial GWs strength as function of its frequency f . Blue curves fix $\xi_h = 0$ and Red curves fix $T_{\text{RH}} = 300 \text{ TeV}$, for k in $[6, 20]$. The sensitivity of several future GWs experiments are shown.

→ GWs leave the same imprint as free-streaming dark radiation on CMB

→ The case of minimal gravitational reheating is excluded by the CMB + BBN bound of $\Omega_{\text{GW}}^0 h^2 \lesssim 10^{-6}$, from excessive GWs as dark radiation.

→ The constraint is relaxed when radiation production is increased by non-minimal gravitational interactions $\xi_h > 0$

Figure 3 : Reheating temperature from gravitational portals as function of k , for different ξ_h

Figure 3 : Reheating temperature from gravitational portals as function of k , for different ξ_h

→ GWs leave the same imprint on the CMB as free-streaming dark radiation

→ The case of minimal gravitational reheating is excluded by the BBN bound of $\Omega_{\text{GW}}^0 h^2 \sim 10^{-6}$, from excessive GWs as dark radiation.

→ The constraint is relaxed when radiation production is increased by non-minimal gravitational interactions $\xi_h > 0$

→ An important part of the parameter space for reheating could be probed by future GWs experiments !

5 - Gravity as a portal to reheating, leptogenesis and DM

Baryogenesis via leptogenesis, Strumia, **0608347**

Graviton portal can handle the production of sterile neutrinos

Interference between tree level decay and vertex + self energy 1-loop order corrections provides a CP violation in the decay of the sterile neutrino.

$$\epsilon \equiv \frac{\Gamma_{N \rightarrow L_\alpha H} - \Gamma_{N \rightarrow \bar{L}_\alpha \bar{H}}}{\Gamma_{N \rightarrow L_\alpha H} + \Gamma_{N \rightarrow \bar{L}_\alpha \bar{H}}} \simeq -\frac{3 \delta_{\text{eff}}}{16\pi} \cdot \frac{m_{\nu_i} m_N}{v^2}$$

$$Y_L \equiv \frac{n_L}{s} = \epsilon \frac{n_N}{s}$$

Considering type I see-saw mechanism with, $v = 174$ GeV (Higgs VEV) and the effective CP violation phase δ_{eff}

Lepton asymmetry, out-of-equilibrium

Inflationary Gravitational Leptogenesis, Co, Mambrini, Olive, **2205.01689**.

Finally, gathering all these results in one “purely” gravitational framework :

$$\mathcal{L} \supset \sqrt{-\tilde{g}} \left[-\frac{M_P^2}{2} \Omega^2 \tilde{\mathcal{R}} + \underbrace{\tilde{\mathcal{L}}_\phi}_{\text{inflaton}} + \tilde{\mathcal{L}}_h + \underbrace{\tilde{\mathcal{L}}_{N_i}}_{\text{RHNs}} \right] \text{ with } (N_1, N_2, N_3)$$

$$\Omega^2 \equiv 1 + \frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2}$$

Non-minimal couplings with gravity

$$\tilde{\mathcal{L}}_{N_i} = -\frac{1}{2} M_{N_i} \bar{N}_i^c N_i - (y_N)_{ij} \bar{N}_i \tilde{H}^\dagger L_j + \text{h.c.}$$

N_1 is the lightest right handed neutrino (RHN) and the DM candidate, assumed to be decoupled from N_2, N_3

N_2, N_3 are much heavier and generate the lepton asymmetry through their gravitational production and out-of-equilibrium decay

$\phi\phi \rightarrow N_1 N_1$ and $SM SM \rightarrow N_1 N_1$
from minimal and non-minimal couplings

$\phi\phi \rightarrow N_2 N_2 (N_3 N_3)$
from minimal and non-minimal couplings

$\phi\phi \rightarrow SM SM$
Non-minimal coupling, for radiation production

Gravitational leptogenesis and DM production simultaneously

M_{N_1} [PeV]	M_{N_2} [GeV]	ξ_h
1.1	1.6×10^{11}	0
2.8	4.0×10^{11}	1
8.7	1.3×10^{12}	10

We choose in this table $k = 6$ as a benchmark. For each ξ on the plot, the range runs over $k \in [6, 20]$ without a significant change.

Gravity as a Portal to Reheating, Leptogenesis and Dark Matter, B. Barman, SC, R. Co, Y. Mambrini, K.A. Olive, 2210.05716

Figure 7 : (M_{N_1}, M_{N_2}) parameter space satisfying simultaneously the observed DM relic abundance (N_1) and the baryon asymmetry (N_2) via gravitational production, asking also for a gravitational reheating.

Conclusion

- Gravitational production puts unavoidable lower limits on particle production during reheating
- Gravitational portals can complete the reheating for steep inflaton potential (large k)
- Primordial GWs are enhanced during reheating when inflaton redshifts faster than radiation (large k)
- GWs enhancement constrain gravitational reheating from excessive dark radiation at BBN
- GWs signal with a distinctive spectrum for different inflation potential near the minimum (different k)
- It provides a minimal framework to produce sterile neutrinos that handle leptogenesis

There is a way to explain DM relic abundance, Baryon asymmetry and Reheating in a framework which involves only gravitational interactions, with non-minimal coupling to gravity !

Thank you for your attention !

APPENDIX

Can arise from **superpotential in no-scale supergravity** :

$$W = 2^{\frac{k}{4}+1} \sqrt{\lambda} M_P^3 \left(\frac{(\phi/M_P)^{\frac{k}{2}+1}}{k+2} - \frac{(\phi/M_P)^{\frac{k}{2}+3}}{3(k+6)} \right)$$

$$V(\phi) = \lambda M_P^4 \left[\sqrt{6} \tanh \left(\frac{\phi}{\sqrt{6} M_P} \right) \right]^k$$

$$A_{S*} \simeq \frac{V_*}{24\pi^2 \epsilon_* M_P^4} \simeq \frac{6^{\frac{k}{2}}}{8k^2 \pi^2} \lambda \sinh^2 \left(\sqrt{\frac{2}{3}} \frac{\phi_*}{M_P} \right) \tanh^k \left(\frac{\phi_*}{\sqrt{6} M_P} \right)$$

λ determined by the **power spectrum amplitude of the CMB "As"**

→ Planck measurements give for $k=2$: $\lambda \sim 10^{-11}$ for $N \sim 50$ e-folds

$$\lambda \simeq \frac{18\pi^2 A_{S*}}{6^{k/2} N_*^2}$$

Class of models : **α -attractor T-model inflation**

Figure 1: Potentials for the T-Model inflation $\tanh^{2n}(\varphi/\sqrt{6})$ for $n = 1, 2, 3, 4$

From *Universality Class in Conformal Inflation*, Kallosh and Linde, **1306.5220**

Particle production

Perturbative reheating : considering an oscillating background field with **small couplings** to the other quantum fields
 → Particle production

Example : Yukawa like interaction

$$\mathcal{L}_{\phi,bath} = y_{\phi} \phi \bar{f} f \Rightarrow \Gamma_{\phi} = \frac{y_{\phi}^2}{8\pi} m_{\phi}$$

Constitute the **primordial bath** that will thermalize

See Freeze-in from preheating, Garcia, Kaneta, Mambrini, Olive, Verner, 2109.13280

Classical **non-perturbative** approach : **preheating**
 Time dependent background coupled to **fields**
 leads to **parametric resonance, tachyonic instabilities** etc...

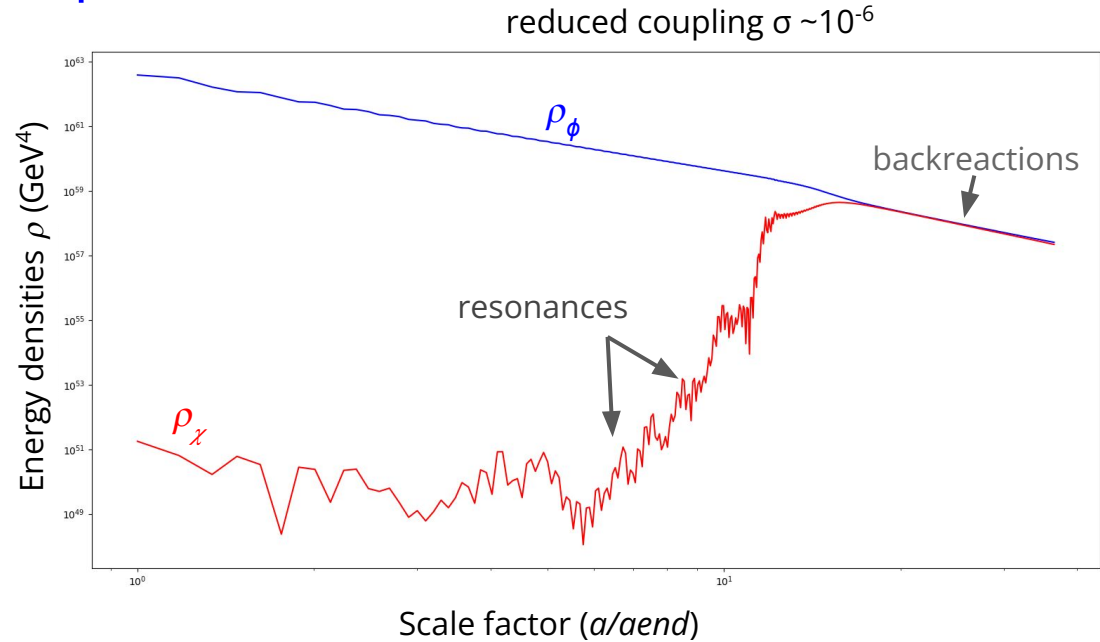

$$\chi_k'' + \left(\frac{k^2}{m_{\phi}^2 a^2} + 2q - 2q \cos(2z) \right) \chi_k = 0$$

EOM for Fourier modes in the oscillating background

Instabilities in the colored regions
 => increasing occupation number of the modes

Preheating : non-perturbative processes

Preheating corresponds to the first oscillations of the background \Rightarrow resonances and exponential production

For large couplings, reach a regime of large backreactions of the fields on the background

Bogoliubov approach

Instead of transition probability, consider the **time evolution of the wave function in the vacuum** while keeping the **effect of curved spacetime**

$$S_\chi = \int d^4x \left[\frac{1}{2} (\tilde{\chi}')^2 - \frac{1}{2} \tilde{\chi} \omega^2 \tilde{\chi} \right] \quad \text{Consider simply a single field in the vacuum}$$

EOM: $\tilde{\chi}'' + \omega^2 \tilde{\chi} = 0$ with $\omega^2 \equiv -\nabla^2 + \boxed{a^2} m_\chi^2 + \boxed{\Delta}$ time dependent frequency!

Then, it is clear that the **Hamiltonian is changing with time through the time dependence in ω** .
 => cannot decompose χ based on the positive/negative frequency in the Fourier space

$$\tilde{\chi}(x) \equiv \int \frac{d^3k}{(2\pi)^{3/2}} e^{i\vec{k}\cdot\vec{x}} \tilde{\chi}_k \quad \xrightarrow{\text{Bogoliubov coefficients}} \quad \begin{cases} u_k = \frac{\boxed{A_k}}{\sqrt{2\omega_k}} e^{-i \int \omega_k d\eta} + \frac{\boxed{B_k}}{\sqrt{2\omega_k}} e^{i \int \omega_k d\eta} \\ \alpha_k \equiv A_k e^{-i \int \omega_k d\eta}, \quad \beta_k \equiv B_k e^{i \int \omega_k d\eta} \end{cases} \quad \xrightarrow{\text{the occupation number is given by}} \quad |\beta_k|^2$$

Phase space distribution of a gravitationally excited scalar field for a range of DM masses, coded by color. The dashed black curve corresponds to the numerical integration of the Boltzmann equation, which is valid for $q > 1$

Boltzmann approach

Assuming that the local background geometry is Minkowskian, we compute transition probability

Initial state inflaton ϕ as a coherently oscillating homogeneous condensate with no momentum

From this, production rate can be computed which is the right hand side of the Boltzmann equations

$$\dot{n}_\chi + 3Hn_\chi = R_{\phi\phi\rightarrow\chi\chi}^{(N)}$$
$$\frac{d\rho_\phi}{dt} + 3H(1 + w_\phi)\rho_\phi \simeq -(1 + w_\phi)\Gamma_{\phi\phi}$$
$$\frac{d\rho_R}{dt} + 4H\rho_R \simeq (1 + w_\phi)\Gamma_{\phi\phi}.$$

Inflaton scattering

Potential near the minimum is a **power k-dependent monomial**

$$V(\phi) = \lambda \frac{\phi^k}{M_P^{k-4}}, \quad \phi \ll M_P$$

Treat the time dependent condensate as a time dependent coupling with an **amplitude and quasi-periodic function which is k-dependent**

$$\phi(t) = \phi_0(t) \cdot \mathcal{P}(t)$$

→ An homogeneous classical field, not a quantum field !

$$V(\phi) = V(\phi_0) \sum_{n=-\infty}^{\infty} \mathcal{P}_n^k e^{-in\omega t} = \rho_\phi \sum_{n=-\infty}^{\infty} \mathcal{P}_n^k e^{-in\omega t}$$

Expand the quasi-periodic function in **Fourier modes**

$$\text{with } \omega = m_\phi \sqrt{\frac{\pi k}{2(k-1)} \frac{\Gamma(\frac{1}{2} + \frac{1}{k})}{\Gamma(\frac{1}{k})}}$$

Each **Fourier mode adds its contribution** to the scattering amplitude **with its energy $E_n = n \cdot \omega$**

DM production in minimal framework

Gravitational portals in the early Universe, SC, Mambrini, Olive, Verner, **2112.15214**

Figure 2 : DM relic, $\Omega h^2 = 0.12$ in the case of a **spin 0 DM**

Figure 3 : DM relic, $\Omega h^2 = 0.12$ in the case of a **spin 1/2 DM**

Radiation production in minimal framework

→ This maximum temperature $T_{\max} \sim 10^{12}$ GeV reached by the bath is unavoidable !

T_{\max} is almost independent of the potential near the minimum (the power k)

	$k = 2$	$k = 4$	$k = 6$
T_{\max}	1.0×10^{12} GeV	7.5×10^{11} GeV	6.5×10^{11} GeV

Reheating is still given by the decay width of the inflaton

Gravitational portals in the early Universe, SC, Mambrini, Olive, Verner, **2112.15214**

Evolution of energy densities of the inflaton (blue), radiation from Yukawa decay (orange) and graviton exchange (green)

Leading order interactions

in Einstein frame

$$\begin{aligned}
 \mathcal{L}_{\text{eff}} = & -\frac{1}{2} \left(\frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_X X^2}{M_P^2} \right) \partial^\mu h \partial_\mu h - \frac{1}{2} \left(\frac{\xi_h h^2}{M_P^2} + \frac{\xi_X X^2}{M_P^2} \right) \partial^\mu \phi \partial_\mu \phi - \frac{1}{2} \left(\frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2} \right) \partial^\mu X \partial_\mu X \\
 & + \frac{6\xi_h \xi_X h X}{M_P^2} \partial^\mu h \partial_\mu X + \frac{6\xi_h \xi_\phi h \phi}{M_P^2} \partial^\mu h \partial_\mu \phi + \frac{6\xi_\phi \xi_X \phi X}{M_P^2} \partial^\mu \phi \partial_\mu X + m_X^2 X^2 \left(\frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2} \right) \\
 & + m_\phi^2 \phi^2 M_P^2 \left(\frac{\xi_X X^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2} \right) + m_h^2 h^2 \left(\frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_X X^2}{M_P^2} \right),
 \end{aligned}$$

$$\mathcal{L}_{\text{non-min.}} = -\sigma_{hX}^\xi h^2 X^2 - \sigma_{\phi X}^\xi \phi^2 X^2 - \sigma_{\phi h}^\xi \phi^2 h^2$$

$$\begin{aligned}
 \sigma_{hX}^\xi = & \frac{1}{4M_P^2} [\xi_h(2m_X^2 + s) + \xi_X(2m_h^2 + s) \\
 & + (12\xi_X \xi_h(m_h^2 + m_X^2 - t))] ,
 \end{aligned}$$

$$\sigma_{\phi h}^\xi = \frac{1}{2M_P^2} [\xi_\phi m_h^2 + 12\xi_\phi \xi_h m_\phi^2 + 3\xi_h m_\phi^2 + 2\xi_\phi m_\phi^2]$$

$$\sigma_{\phi X}^\xi = \frac{1}{2M_P^2} [\xi_\phi m_X^2 + 12\xi_\phi \xi_X m_\phi^2 + 3\xi_X m_\phi^2 + 2\xi_\phi m_\phi^2]$$

$$\mathcal{S}_J = \int d^4x \sqrt{-\tilde{g}} \left[-\frac{M_P^2}{2} \Omega^2 \tilde{\mathcal{R}} + \tilde{\mathcal{L}}_\phi + \tilde{\mathcal{L}}_h + \tilde{\mathcal{L}}_{N_i} \right] \quad \text{with} \quad \begin{cases} \tilde{\mathcal{L}}_\phi = \frac{1}{2} \partial_\mu \phi \partial^\mu \phi - V(\phi) \\ \tilde{\mathcal{L}}_h = \frac{1}{2} \partial_\mu h \partial^\mu h - V(h) \\ \tilde{\mathcal{L}}_N = \frac{i}{2} \bar{N}_i \overleftrightarrow{\nabla} N_i - \frac{1}{2} M_{N_i} \overline{(\mathcal{N})}^c{}_i N_i + \tilde{\mathcal{L}}_{\text{yuk}} \\ \tilde{\mathcal{L}}_{\text{yuk}} = -y_{N_i} \bar{N}_i \widetilde{H}^\dagger \mathbb{L} + \text{h.c.}, \end{cases}$$

and

$$\Omega^2 \equiv 1 + \frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2}$$

→
in the Einstein
frame

$$\mathcal{S}_E = \int d^4x \sqrt{-g} \left[-\frac{M_P^2}{2} \mathcal{R} + \frac{K^{ab}}{2} g^{\mu\nu} \partial_\mu S_a \partial_\nu S_b - \frac{1}{\Omega^4} (V_\phi + V_h) + \frac{i}{2} \bar{N}_i \overleftrightarrow{\nabla} N_i - \frac{1}{2\Omega} M_{N_i} \bar{N}_i^c N_i + \frac{1}{\Omega} \mathcal{L}_{\text{yuk}} \right].$$

$$\mathcal{L}_{\text{non-min.}} = -\sigma_{hN_i}^\xi h^2 \bar{N}_i^c N_i - \sigma_{\phi N_i}^\xi \phi^2 \bar{N}_i^c N_i$$

→
Leading order
interactions of RHN

$$\sigma_{\phi N_i}^\xi = \frac{M_{N_i}}{2M_P^2} \xi_\phi$$

$$\sigma_{hN_i}^\xi = \frac{M_{N_i}}{2M_P^2} \xi_h.$$

DM (N_1) production

Lower limits are coming from inflaton contribution

Upper limits are coming from thermal contribution

Figure 5 : Lines correspond to the *observed DM relic abundance, all gravitational contributions added*, for different M_{N_1} . Shaded regions correspond to under abundance of DM.

Baryon asymmetry from leptogenesis (N_2)

Lepton asymmetry is converted into a **baryon asymmetry** :

$$Y_B = \frac{28}{79} Y_L \simeq 3.5 \times 10^{-4} \delta_{\text{eff}} \frac{n_N}{s} \left(\frac{m_{\nu_i}}{0.05 \text{ eV}} \right) \left(\frac{M_{N_2}}{10^{13} \text{ GeV}} \right)$$

Gravity as a Portal to Reheating, Leptogenesis and Dark Matter, B. Barman, SC, R. Co, Y. Mambrini, K.A. Olive, 2210.05716

Figure 6 : Lines corresponding to the **observed baryon asymmetry** $Y_B \simeq 8.7 \times 10^{-11}$ for different M_{N_2}

Non-canonical kinetic term

$$\mathcal{S} = \int d^4x \sqrt{-g} \left[-\frac{M_P^2}{2} R + \frac{1}{2} K^{ij} g^{\mu\nu} \partial_\mu S_i \partial_\nu S_j - \frac{V_\phi + V_h + V_X}{\Omega^4} \right] \quad \text{in Einstein frame}$$

with

$$\Omega^2 \equiv 1 + \frac{\xi_\phi \phi^2}{M_P^2} + \frac{\xi_h h^2}{M_P^2} + \frac{\xi_X X^2}{M_P^2} \quad \text{and} \quad K^{ij} = 6 \frac{\partial \log \Omega}{\partial S_i} \frac{\partial \log \Omega}{\partial S_j} + \frac{\delta^{ij}}{\Omega^2} \quad \text{non-canonical kinetic term}$$

In general, it is impossible to make a field redefinition that would bring it to the canonical form, unless all three non-minimal couplings vanish.

$$\frac{|\xi_\phi| \phi^2}{M_P^2}, \quad \frac{|\xi_h| h^2}{M_P^2}, \quad \frac{|\xi_X| X^2}{M_P^2} \ll 1$$

In the **small-field limit**, we can expand the action in powers of M_p^{-2} and **obtain canonical kinetic term and deduce the leading-order interactions** induced by the non-minimal couplings.

Non-minimal couplings bounds

→ Small field approximation is valid if: $\sqrt{|\xi_S|} \lesssim M_P / \langle S \rangle$ with $S = \phi, h, X$

→ Since at the end of inflation we have $\phi_{\text{end}} \sim M_P$ and that inflaton field is decreasing during the reheating

$$\Rightarrow |\xi_\phi| \lesssim 1$$

→ Since our perturbative computations involve effective couplings in the Einstein frame that depend on all ξ , the small value of ξ_ϕ can be compensated by ξ_h . Current constraints on ξ_h from collider experiments is $\xi_h < 10^{15}$

See for example *Cosmological Aspects of Higgs Vacuum Metastability*, Tommi Markkanen, Arttu Rajantie, Stephen Stopyra, **1809.06923**

→ On the other hand, to prevent the EW vacuum instability at high energy scale, during inflation, we can invoke stabilization through effective Higgs mass from the non-minimal coupling : $\xi_h > 10^{-1}$

→ In the case of Higgs inflation, ξ_h is fixed from CMB (Planck)

See F. L. Bezrukov and M. Shaposhnikov, Phys. Lett. B (2008)

Sphalerons and baryogenesis

→ Anomalous baryon number violating processes are unsuppressed at high temperatures : the so called non-perturbative sphaleron transitions violate (B+L) but conserve (B-L).

N.S. Manton, Phys. Rev. (1983) , F.R. Klinkhammer and N.S. Manton, Phys. Rev. D (1984), V.A. Kuzmin, V.A. Rubakov and M.E. Shaposhnikov, Phys. Lett. B (1985)

→ Primordial (B-L) asymmetry can be realized as a lepton asymmetry generated by the out-of equilibrium decay of heavy right-handed Majorana neutrinos. L is violated by Majorana masses, while the necessary CP violation comes with complex phases in the Dirac mass matrix of the neutrinos

M. Fukugita and T. Yanagida, Phys. Lett. B (1986)

$$Y_B = \left(\frac{8N_f + 4N_H}{22N_f + 13N_H} \right) Y_{B-L}$$
