

HHH workshop

14-16th of July 2023 Dubrovnik

(A Few) Experimental Thought HHHs

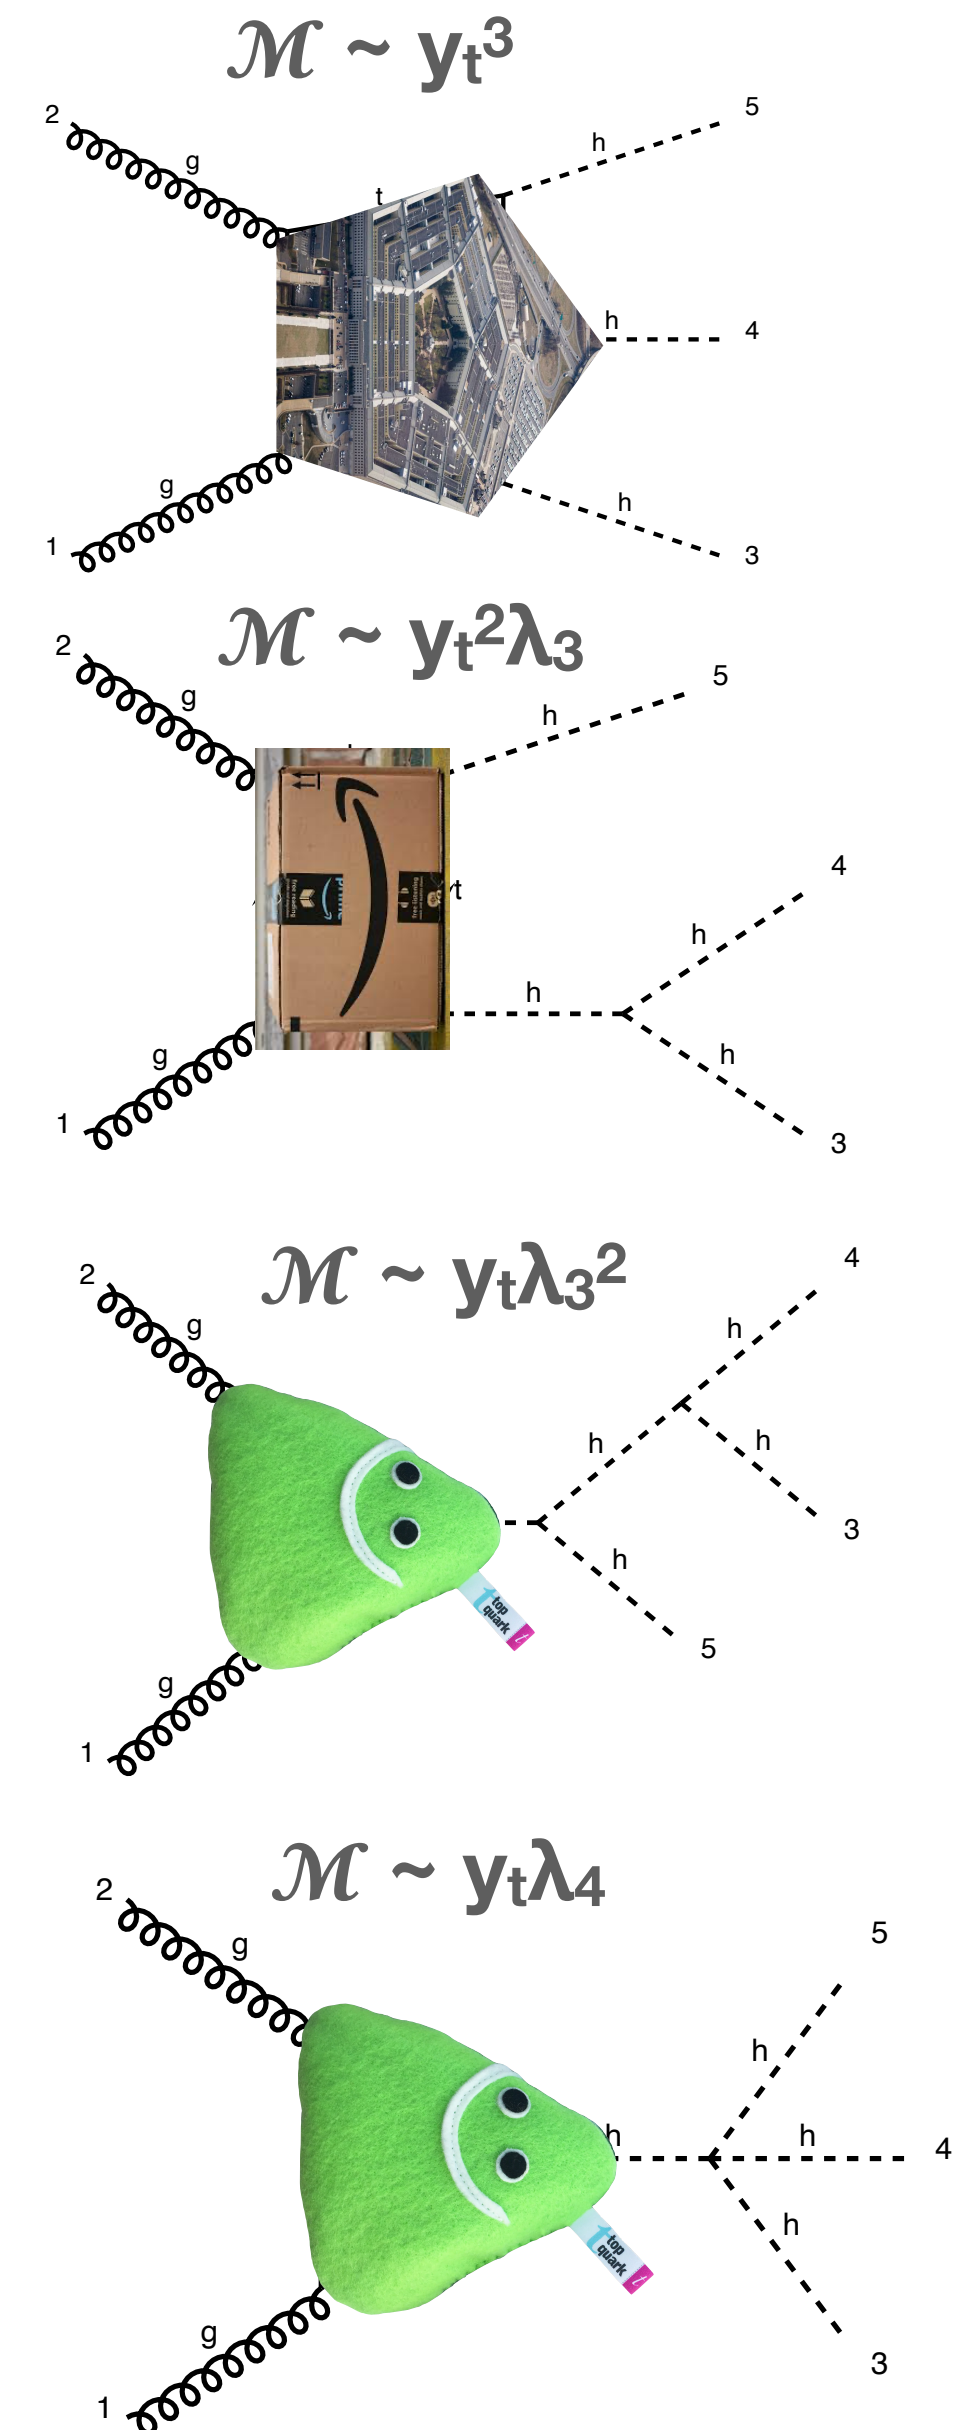

HHH Workshop - Dubrovnik, Croatia, 15.07.23

Greg Landsberg, Brown University

Diagrammatics

- LO: 50 top quark loop diagrams + 50 bottom loop ones; ignore the latter
- Four classes:
 - **Pentagon:** $\sim y_t^3$ - 24 diagrams; destructively interfere with "signal"
 - **Box:** $\sim y_t^2 \lambda_3$ - 18 diagrams, proportional to λ_3 - destructive int.
 - **Triangle:** $\sim y_t \lambda_3^2$ - 6 diagrams, proportional to λ_3^2 - destructive int.
 - **Quartic:** $\sim y_t \lambda_4$ - 2 diagrams, sensitive to quartic coupling - don't interfere with other diagrams to the first order
- N.B. Given the $\lambda_3 = \lambda_4 = 0.13$ in the SM, box diagrams dominate in the SM, but not necessarily at large λ_3
 - Challenge - identify the phase space where triangular diagrams dominate - might enhance the sensitivity to large λ_3

Branching Fractions

- $H(bb) = 58.1\%$, $H(\tau\tau) = 6.26\%$, $H(WW) = 21.5\%$, $H(gg) = 8.18\%$, $H(ZZ) = 2.6\%$, $H(\gamma\gamma) = 0.23\%$
- $\sigma_{HHH}(14 \text{ TeV, NNLO}) = 0.1 \text{ fb}$
- Aim at $\sigma^{95} = 100 \times \sigma_{HHH} = 10 \text{ fb}$; Run 2 $\times \sigma^{95} \sim 1000$ events; Run 2 $\times \sigma^{95} \times \epsilon \sim 100$ events
- To set a limit, need expected yield of 3 signal events: do not consider $\text{Br} < 3\%$ for now
- **$HHH \rightarrow 6b: 19.5\%$**
- **$HHH \rightarrow bbbb\tau\tau: 6.3\%$; $bbbb\tau_h\tau_h: 2.7\%$**
- **$HHH \rightarrow bbbbWW \rightarrow 4b4j: 9.9\%$**
- **$HHH \rightarrow bbbb\gamma\gamma \rightarrow 4b2j: 8.3\%$**
- $HHH \rightarrow bbbbWW \rightarrow 4b2j\ell\nu: 5.9\%$
- ~~$HHH \rightarrow bb\tau\tau WW \rightarrow 2b2\tau4j: 2.1\%$~~
- ~~$HHH \rightarrow bbbbWW \rightarrow 4b2\ell2\nu: 0.9\%$~~
- ~~$HHH \rightarrow bb\tau\tau\tau\tau: 0.68\%$~~
- ~~$HHH \rightarrow bbbb\gamma\gamma: 0.23\%$~~

41% - Focus on these topologies: 4b + jets

N.B.1: this is SIMPLER than $HH \rightarrow 4b$

All the techniques developed for that analysis can be reused if desired
Backgrounds by construction are order of magnitude or more lower

N.B.2: $WW \rightarrow \ell\nu jj$, while promising, doesn't have a mass peak

Jet Merging

- Merged jets help tremendously against combinatorics:
 - $HHH \rightarrow 6b$: $C^2_6 \times C^2_4 \times C^2_2 / 3! = 15 \times 6 \times 1 / 6 = 15$ combinations
 - $HHH \rightarrow 4b+J$: $C^2_4 \times C^2_2 / 2! = 6 \times 1 / 2 = 3$ combinations!
 - $HHH \rightarrow 2b+2J$ and $HHH \rightarrow 3J = 1$ combination each!!
- N.B.1. Average Higgs boson p_T in HHH production ~ 200 GeV - boosted topologies are not rare
- N.B.2.: for a 200 GeV p_T , $\theta \approx 2/\gamma \approx 1.25$, so $R \sim 1.0$ jets are effective in catching Higgs boson decays

Osama Karkout's talk

Toward Merged Topologies

- Our experience: merged jet topologies offer better performance than resolved ones
 - Smaller combinatorics
 - Substructure variables are apparently more powerful than what we use in the resolved case
- Idea: why bother with resolved, fully merged, and partially merged topologies?
 - Work with CA1.5-2.0 jets and have at least two out of three Higgs boson decays merged!
 - No combinatorics, and the advantage of using jet substructure techniques!

Resonances

- We know that resonances could easily boost the HHH cross section by 2 orders of magnitude (HHH \rightarrow HH)
- E.g., 2101.0031 (2RSM)
 - $pp \rightarrow h_3 \rightarrow h_2 h_1 \rightarrow h_1 h_1 h_1$ ($h_1 = H(125)$)
 - $M_3 = 500$ GeV, $M_2 = 300$ GeV, $\sigma \sim 40$ fb
- At the LHC, we are good at looking at $pp \rightarrow X \rightarrow AB$ (jj , ll , $\gamma\gamma$, VV , VH , HH , $V\gamma$, $H\gamma$, Va , aa) as well as more complex decays for pair production: e.g., $pp \rightarrow gg \rightarrow 6j$
- We rarely do single resonance searches decaying in three objects
 - The $Z \rightarrow XY$ search program is still in its infancy
 - Recent example: CMS search PAS EXO-22-008 for $pp \rightarrow X \rightarrow jjj$ (either directly $Z' \rightarrow ggg$, or via an intermediate resonance $g_{KK} \rightarrow Rg \rightarrow ggg$ or $q^* \rightarrow qV \rightarrow qqq$) - first of a kind at colliders (cf. ~ 50 $pp \rightarrow X \rightarrow jj$ searches from ATLAS+CMS)
- As a side remark, we should also do VVH and VHH searches!
 - The latter gives direct access to κ_{2V}

Triggers

- In the approach I suggest, we need the same triggers (and largely the analysis!) as (boosted) $HH \rightarrow 4b$ search
- As you saw, CMS had rather efficient triggers in Run 2, and have installed even more efficient (partially parked) triggers in Run 3
- General trigger strategy: $H_T \sim 300 \text{ GeV} + 2\text{-}3 \text{ b tagged jets (PNet)}$
- If one wishes to also pursue the $4b+2j+l\nu$ channel, isolated single-lepton triggers would suffice

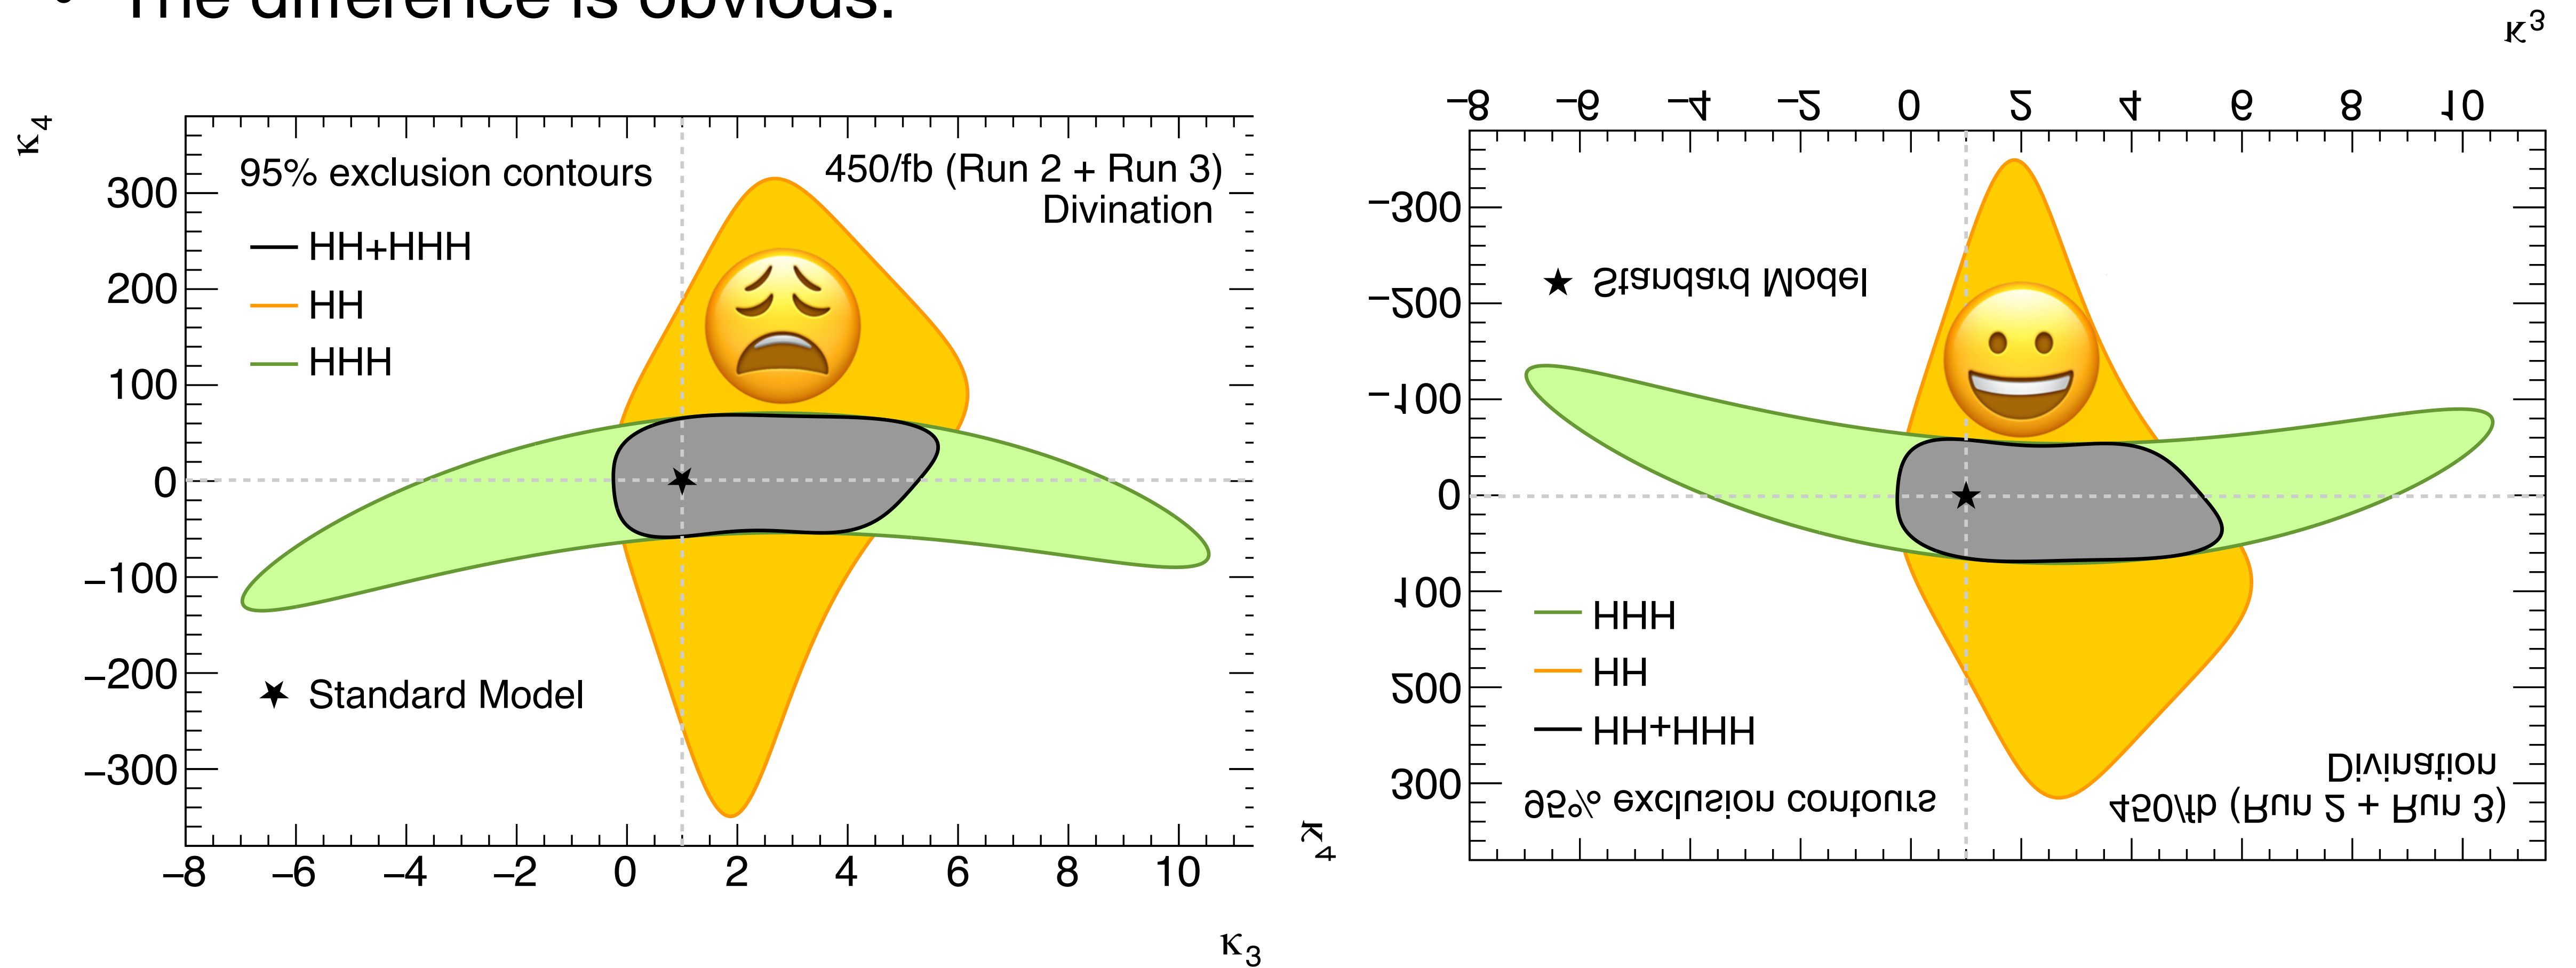

My Conclusions

- Think before you get engaged into analysis!
- The difference is obvious:

My Conclusions

- Think before you get engaged into analysis!

ChatGPT Conclusions

- In the realm of particles so grand,
Where mysteries lie in each strand,
The Higgs boson takes its place,
With secrets held in its embrace.
- Its self-coupling, a subtle dance,
A tryst of particles in cosmic expanse.
Yet direct measurements remain unseen,
As scientists strive to grasp its serene.
- Indirect constraints like whispers told,
Unveiling truths in the particles' fold.
With bounds and limits, we seek to find,
The Higgs self-coupling, an enigma entwined.
