# Motivation for PID in jets

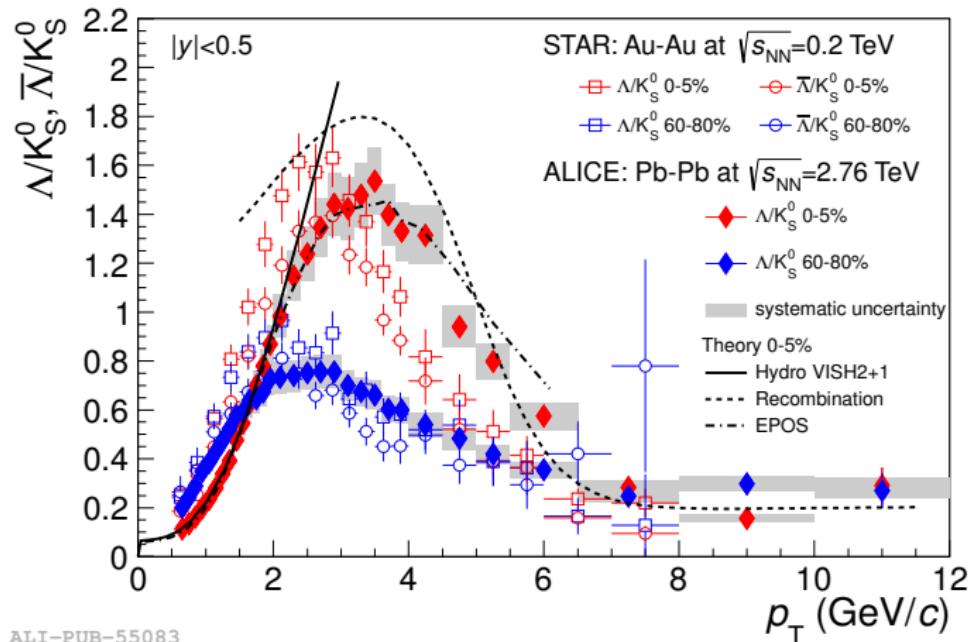

- ▶ Baryon-to-meson ratio is enhanced in A–A and p–A collisions (RHIC, LHC).
- ▶ This phenomenon cannot be explained by fragmentation in vacuum.
- ▶ What is the effect of QGP on hadronization mechanism(s) in jets?
- ▶ What are the mechanisms (parton recombination)?

Phys. Rev. Lett. **111** (2013) 222301

# Comparison of data with models

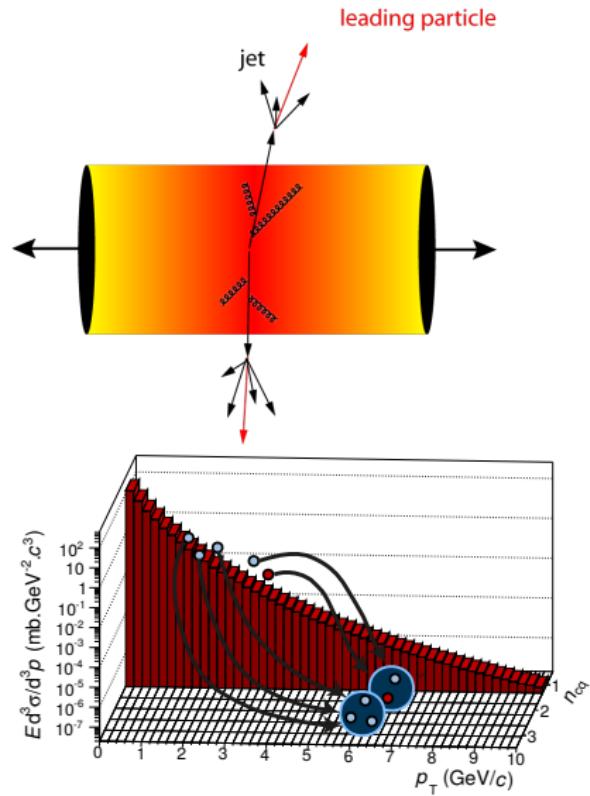

Phys. Rev. Lett. **111** (2013) 222301

# Motivation for PID in jets

We aim to understand the origin(s) of the  $\Lambda/K_S^0$  enhancement by separating hadrons produced in hard processes (jets) from hadrons produced in soft processes (underlying event).

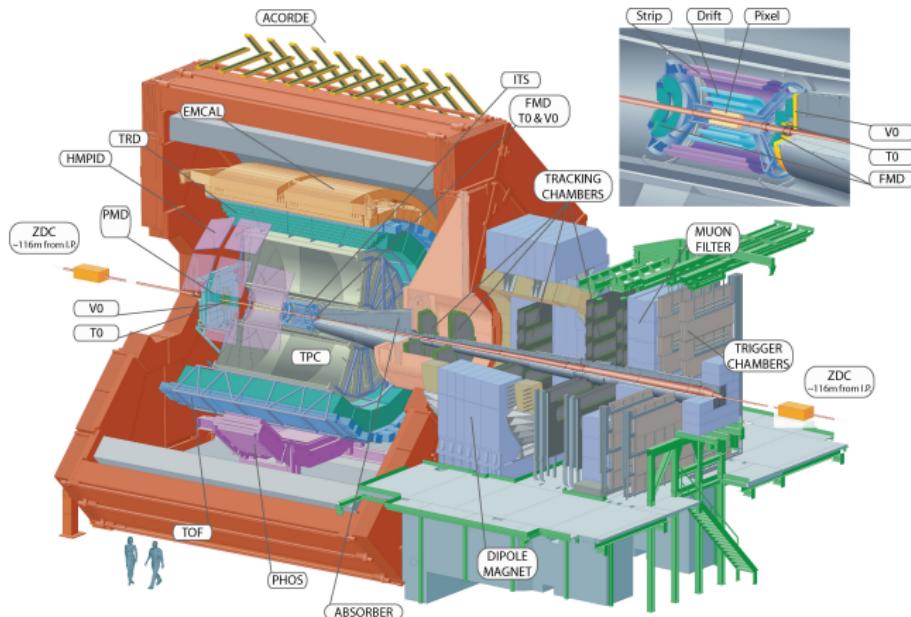

Is the baryon-to-meson ratio enhanced due to the collective effects in the plasma (parton recombination, radial flow,...) or is it (also) due to a modification of the jet fragmentation in the medium?

- ▶ jet fragmentation  
A high- $p_T$  parton from hard scattering fragments into hadrons.
- ▶ parton recombination  
Multiple partons cluster together to form a hadron.

# ALICE

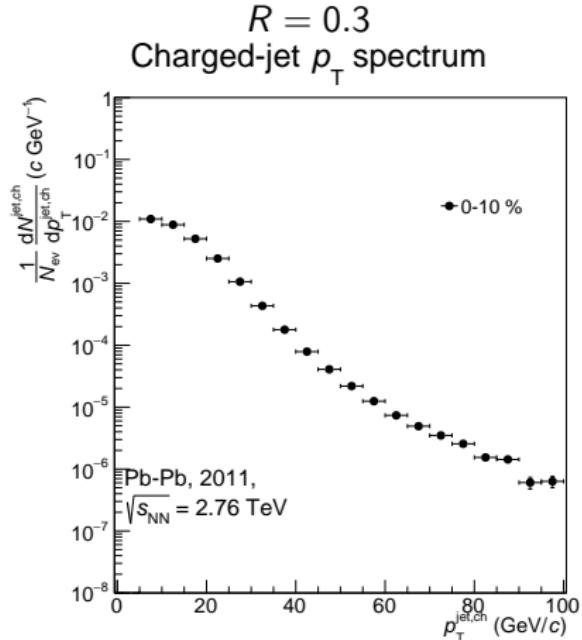

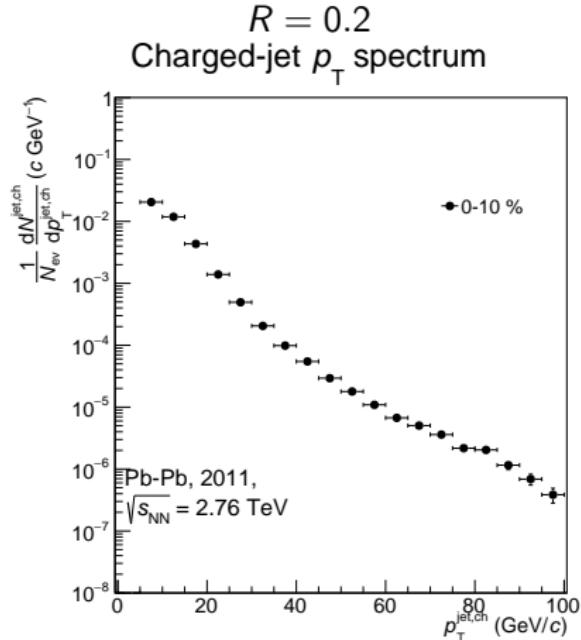

- ▶ collisions studied: p-p at  $\sqrt{s} = 7 \text{ TeV}$ , p-Pb at  $\sqrt{s_{\text{NN}}} = 5.02 \text{ TeV}$ , Pb-Pb at  $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$
- ▶ tracking of charged particles by ITS & TPC in magnetic field of 0.5 T
- ▶ centrality estimated from the multiplicity of charged particles in the detectors at forward and backward pseudorapidities

# Analysis of charged jets

- ▶ track selection
  - ▶ charged primary particles
  - ▶  $p_T^{\text{track}} > 150 \text{ MeV}/c$
  - ▶ uniform in  $\phi \times \eta$ ,  $|\eta_{\text{track}}| < 0.9$
- ▶ raw-jet reconstruction
  - ▶ anti- $k_t$  algorithm
  - ▶ resolution parameter  $R = 0.2, (0.3, 0.4)$
- ▶ subtraction of average soft background
  - ▶ average background density  $\rho$  estimated from the median  $k_t$  cluster
  - ▶  $p_T^{\text{jet, ch, corr}} = p_T^{\text{jet, ch, raw}} - \rho A_{\text{jet, ch}}$ , (where  $A_{\text{jet, ch}}$  is jet area)
- ▶ signal-jet selection (good candidates for hard scattering)
  - ▶  $p_T^{\text{leading track}} > 5 \text{ GeV}/c$  (only Pb–Pb)
  - ▶  $A_{\text{jet, ch}} > 0.6\pi R^2$
- ▶ further  $p_T^{\text{jet, ch}}$  corrections
  - ▶ background anisotropy (intra-event  $p_T$  fluctuations)
  - ▶ detector response

# Jet spectra

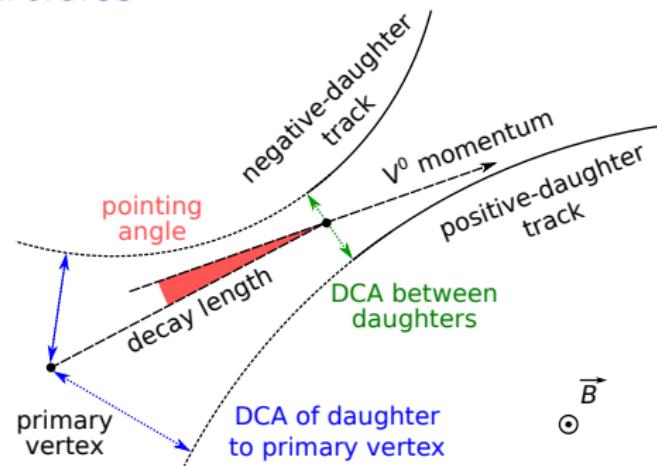

Larger  $R \Rightarrow$  harder spectrum (but softer jets at a given  $p_T^{\text{jet}}$ ).

# Analysis of neutral strange particles

Strange neutral particles decaying into two charged daughter particles

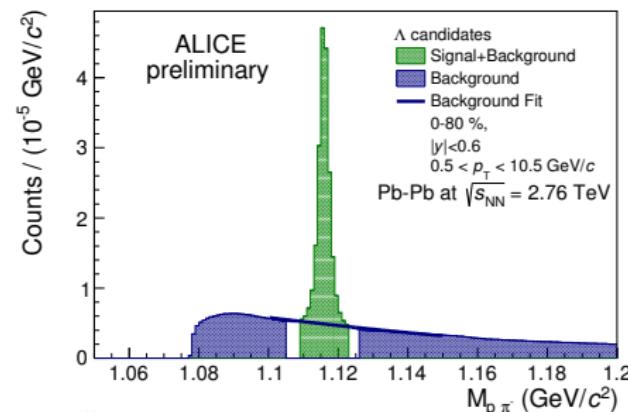

- ▶ meson  $K_S^0 \rightarrow \pi^+ + \pi^-$  (BR 69 %)
- ▶ baryon  $\Lambda \rightarrow p + \pi^-$  (BR 64 %)

Mother  $V^0$  particle reconstructed using topology of its V-shaped decay.

Combinatorial background suppressed by cuts on decay parameters.

Signal yield extracted from the invariant-mass distribution.

# Strange particles in jets

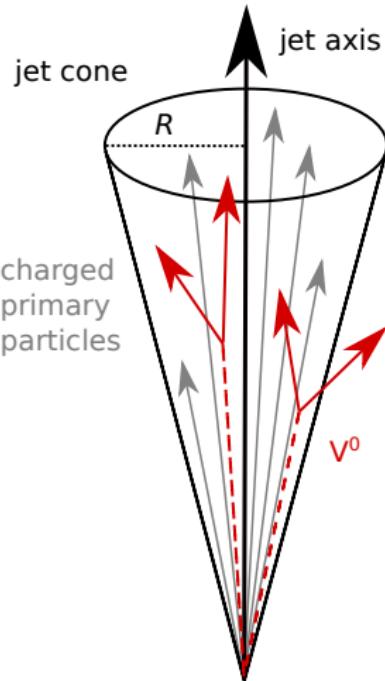

## Analysis steps

- ▶  $V^0$  candidate selection
- ▶ candidate-jet matching ( $V^0$ s in jet cones)

$$\sqrt{(\phi_{V^0} - \phi_{\text{jet, ch}})^2 + (\eta_{V^0} - \eta_{\text{jet, ch}})^2} < R,$$

$$|\eta_{\text{jet, ch}}|^{\max} < |\eta_{V^0}|^{\max} - R$$

- ▶ candidate-UE matching ( $V^0$ s in events without selected jets with  $p_T^{\text{jet, ch}} > 5 \text{ GeV}/c$ )
- ▶ signal extraction (invariant-mass distribution)
- ▶ efficiency correction (in jet cones, in UE)
- ▶ subtraction of  $V^0$ s in UE
- ▶ subtraction of  $V^0$ s coming from decays of jet constituents ( $\Xi \rightarrow \Lambda$ ), i.e. “feed-down” correction

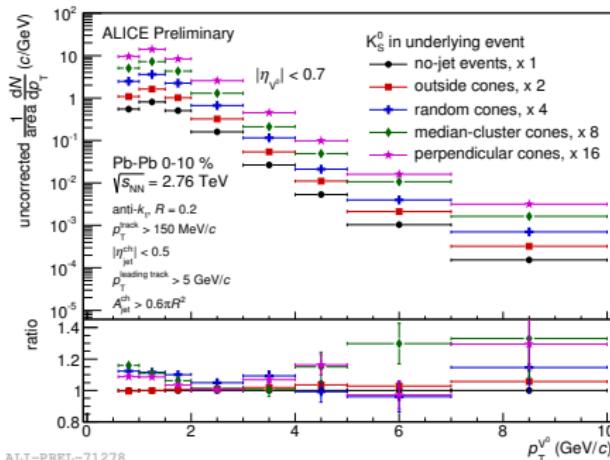

# Estimation of $V^0$ 's in the underlying event

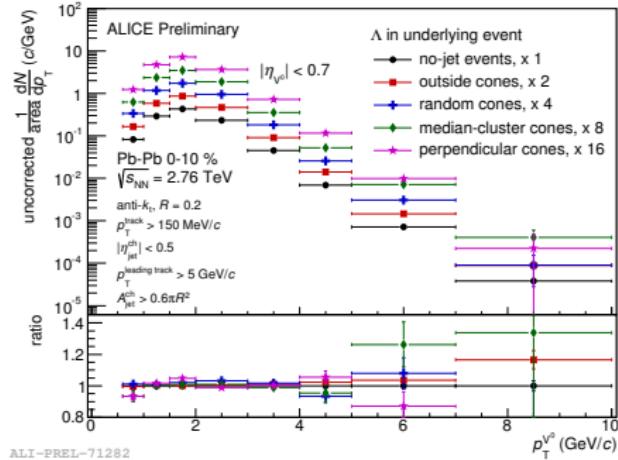

- ▶ no-jet events:  $V^0$ 's in events with no selected jets
- ▶ outside cones:  $V^0$ 's outside jet cones
- ▶ random cones:  $V^0$ 's in a randomly oriented cone
- ▶ median-cluster cones:  $V^0$ 's in the cone of the median  $k_t$ -cluster
- ▶ perpendicular cones:  $V^0$ 's in cones perpendicular to the jet in azimuth

Methods differ in regions, events, statistics, efficiency.

$K_S^0$

$\Lambda$

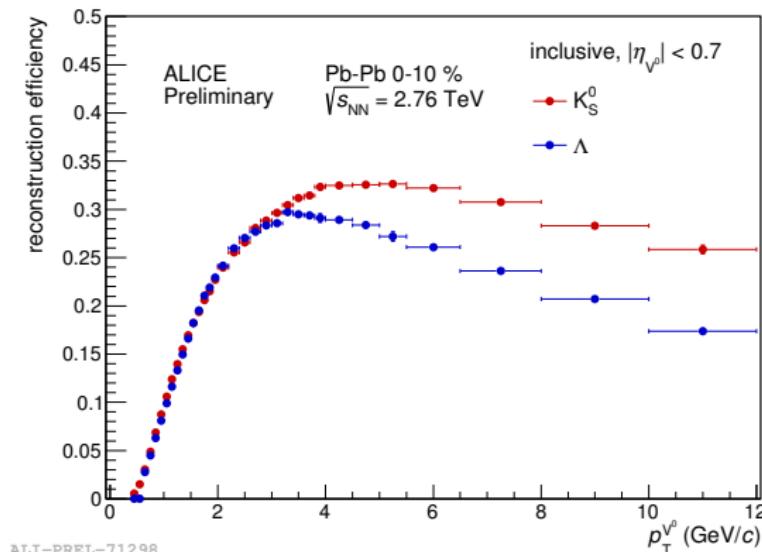

ALI-PREL-71278

# Reconstruction efficiency of $V^0$ particles

- ▶ Reconstruction efficiency depends strongly on  $p_T^{V^0}$  and  $\eta_{V^0}$ .
- ▶ Shape of the measured  $\eta_{V^0}$  distribution depends on the selection criteria.
- ▶ Not enough statistics to apply efficiency correction in 2D ( $p_T^{V^0} \times \eta_{V^0}$ ).

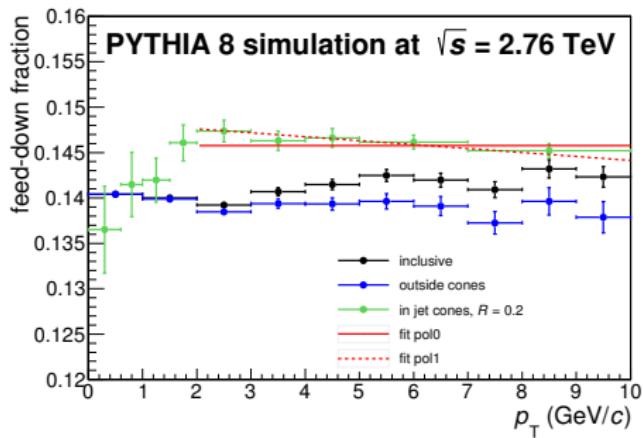

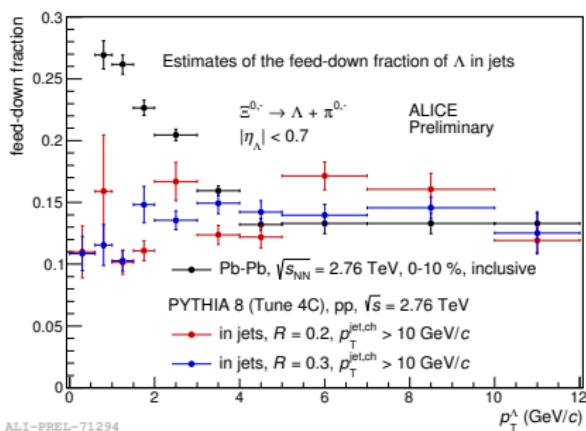

⇒ Efficiency of inclusive  $V^0$ 's is scaled (in 2D) to get efficiency in jet cones and UE (in 1D).

# Feed-down in jets

Feed-down fraction of  $\Lambda$  in jets estimated from:

- ▶ inclusive  $\Lambda$  (Pb–Pb-like),
- ▶ jets generated by PYTHIA 8 (p–p-like).

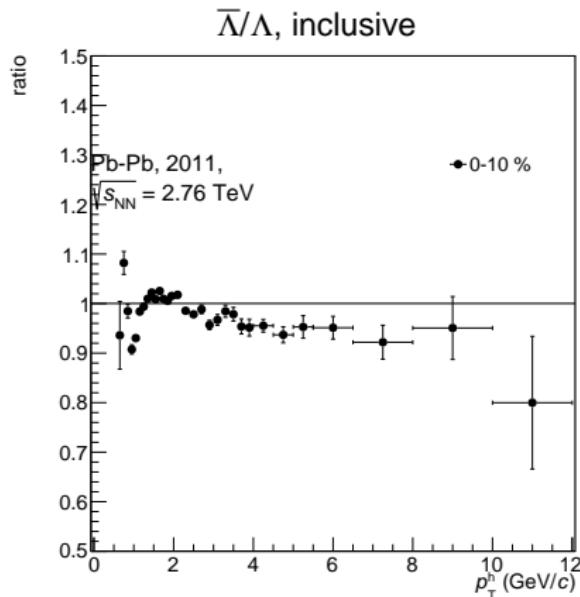

## Estimation of systematic uncertainties

The systematic uncertainties are studied for the following sources:

- ▶ reconstruction efficiency of  $V^0$ 's (selection cuts applied on  $V^0$  candidates),
- ▶ signal extraction (fitting parameters),
- ▶ subtraction of spectra of  $V^0$ 's in UE (5 methods),
- ▶ subtraction of feed-down in jets (inclusive vs PYTHIA),
- ▶ material budget (detector model),
- ▶ fluctuations of UE (jet embedding).

## Open issue: $\Lambda$ - $\bar{\Lambda}$ asymmetry

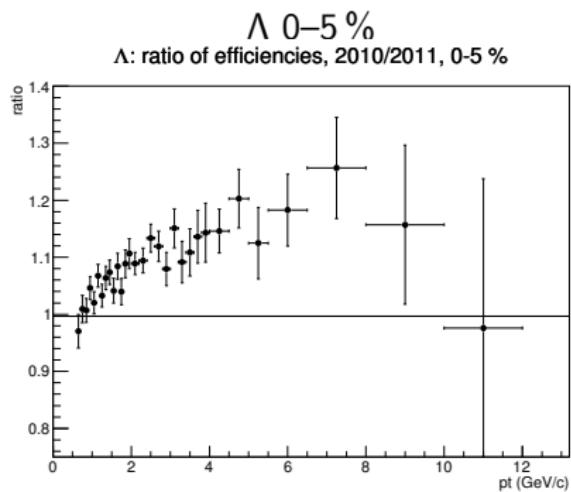

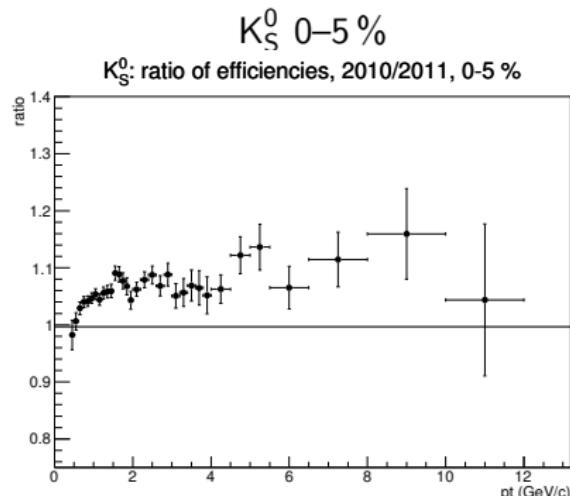

Discrepancy between inclusive spectra of  $\Lambda$  and  $\bar{\Lambda}$ .

Strong dependence on the polarity of magnetic field and the sign of  $\eta$ .  
Additional 6 % (symmetric) considered as systematics.

# Open issue: discrepancy in MC between runs 2010, 2011

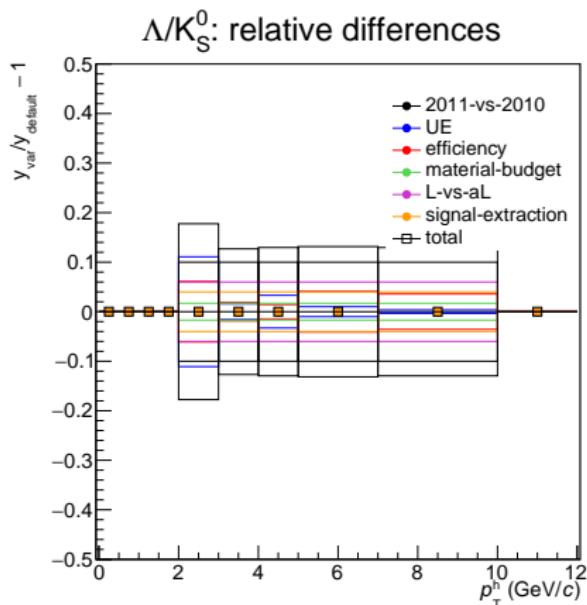

Differences in spectra traced back to the reconstruction efficiencies.

Effects of  $\lesssim 10\%$  for  $K_S^0$ ,  $\lesssim 20\%$  for  $\Lambda$ , partially cancel out in  $\Lambda/K_S^0$ .  
Observed also in other analyses (charged-particle spectra, correlations).  
Additional 10 % (symmetric) considered as systematics.

## Systematics: combined

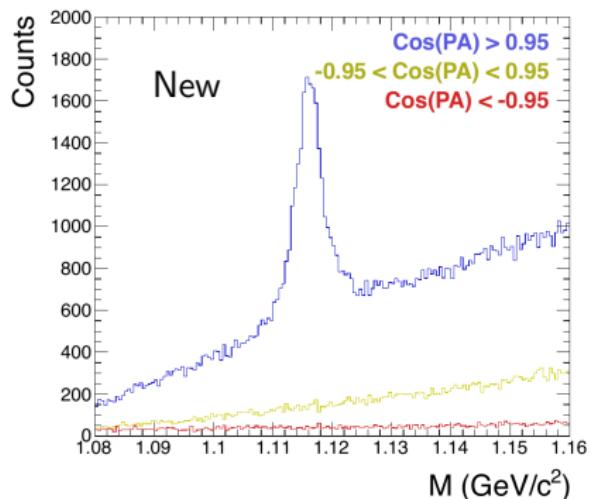

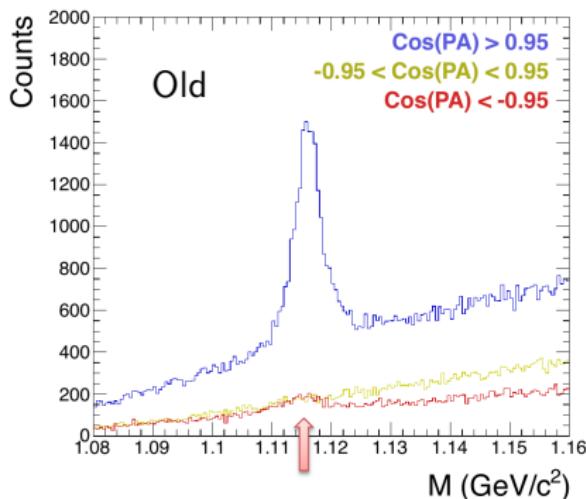

$$R = 0.2, p_T^{\text{jet},\text{ch}} > 10 \text{ GeV}/c, (\Lambda + \bar{\Lambda})/2K_S^0$$

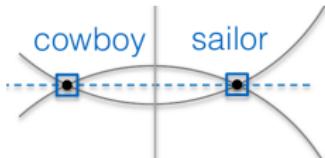

Uncertainties from different sources (except feed-down) are combined in squares and considered symmetric.

# $V^0$ vertexer problem

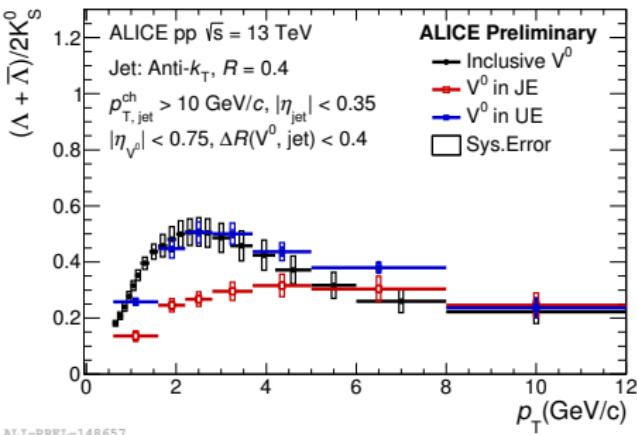

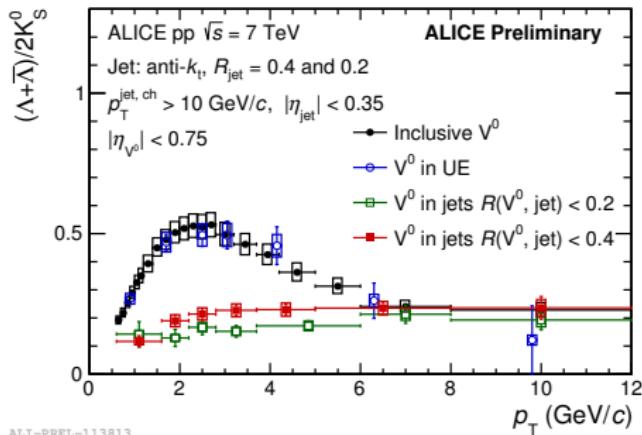

- ▶ There may be two candidates for the point of closest approach (“cowboy/sailor” configuration).
- ▶ Old vertexer: sailor misidentified as cowboy  $\rightarrow \text{CPA} \approx -1 \rightarrow \text{rejected}$ .
- ▶ New vertexer: Select the point with the smallest DCA calculated in 3D.

- ▶  $\Rightarrow$  Better MC–real data matching.
- ▶ Cause of losing sailors with the old vertexer still unclear.

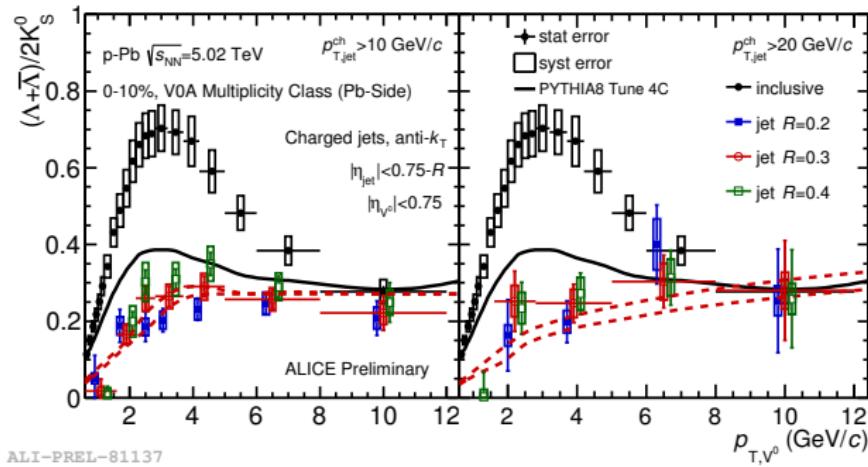

# $\Lambda/K_S^0$ ratio in jets in p-p at $\sqrt{s} = 7 \text{ TeV}$ and $13 \text{ TeV}$

- ▶ The ratio in UE is consistent with the inclusive ratio.
- ▶ The ratio in jets is clearly different from the inclusive ratio at low and intermediate  $p_T^{V^0}$ .
- ▶ A slight increase of the ratio in jets with increasing  $R$ .

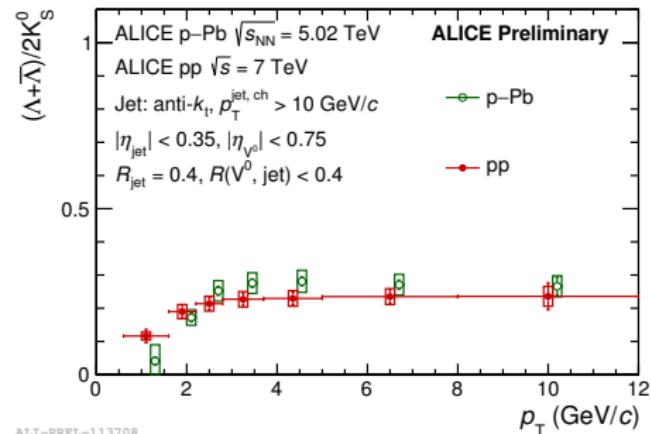

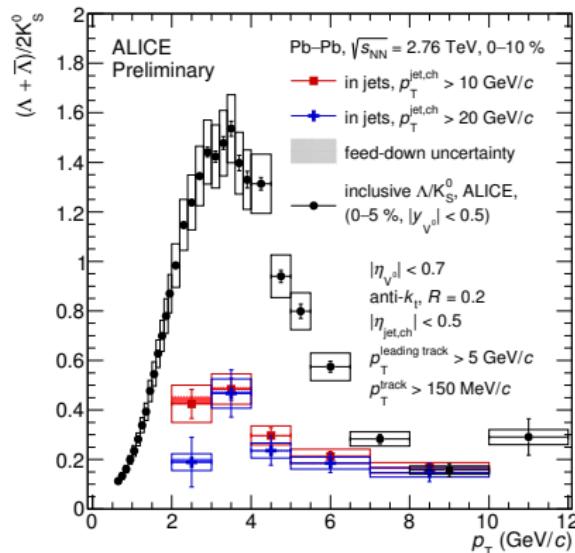

# $\Lambda/K_S^0$ ratio in jets in p-Pb at $\sqrt{s_{\text{NN}}} = 5.02 \text{ TeV}$ (high-multiplicity collisions, 0–10 %)

The ratio in jets

- ▶ is clearly different from the inclusive ratio at low and intermediate  $p_T^{V^0}$ ,
- ▶ is different from the inclusive ratio in PYTHIA (black line),
- ▶ is similar to the ratios in PYTHIA jets (red dashed lines),
- ▶ shows no significant dependence on  $p_T^{\text{jet},\text{ch}}$  and a slight dependence on  $R$ .

# $\Lambda/K_S^0$ ratio in jets in Pb–Pb at $\sqrt{s_{NN}} = 2.76$ TeV ( $7.4 \times 10^6$ central collisions, 0–10 %)

ALI-PREL-93799

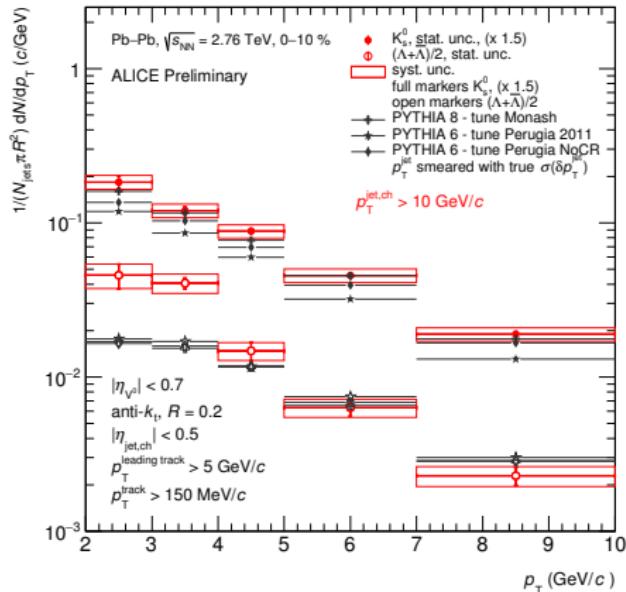

The ratio in jets

- is clearly different from the inclusive ratio at low and intermediate  $p_{\text{T}}^{V^0}$ ,
- shows no significant dependence on  $p_{\text{T}}^{\text{jet},\text{ch}}$ ,
- is consistent with the ratio in jets in p–Pb and p–p at  $p_{\text{T}}^{V^0} > 4$  GeV/ $c$ .

# $K_S^0$ , $\Lambda$ spectra in jets in Pb–Pb

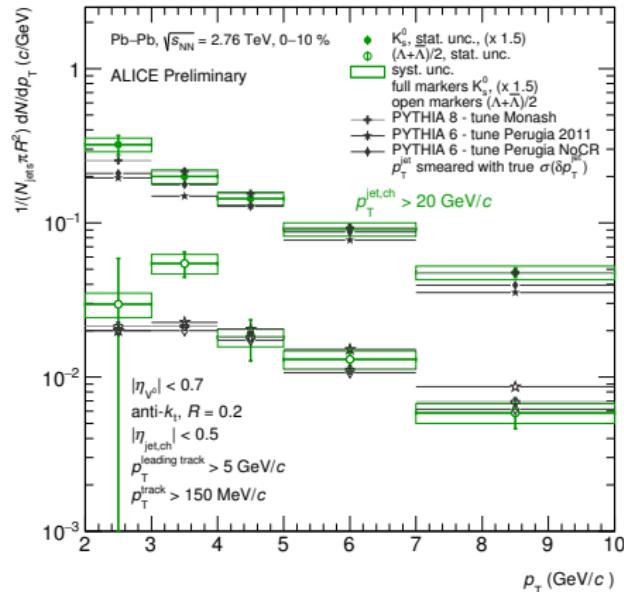

comparison to PYTHIA smeared with  $p_T^{\text{jet, ch}}$  fluctuations

$p_T^{\text{jet, ch}} > 10 \text{ GeV}/c$

ALI-PREL-112798

$p_T^{\text{jet, ch}} > 20 \text{ GeV}/c$

ALI-PREL-112802

- ▶ Same slopes of spectra from measurement and from PYTHIA.
- ▶ Enhancement for  $\Lambda$  at  $p_T^{\Lambda} < 4 \text{ GeV}/c$ .

## Summary and outlook

ALICE has performed the first measurement of the  $\Lambda/K_S^0$  ratio in charged jets in p-p, p-Pb and Pb-Pb collisions at the LHC.

### Results

- ▶ In every collision system, the  $\Lambda/K_S^0$  ratio in jets is significantly smaller than the inclusive ratio (and the UE).
- ▶ The  $\Lambda/K_S^0$  ratios in jets are consistent within uncertainties in all collision systems for  $p_T^{V^0} > 4 \text{ GeV}/c$ .
- ▶ The dominant source of the enhancement are soft processes associated with collective behaviour.
- ▶ A potential modification of jet fragmentation seems to be restricted to the region  $p_T^{V^0} < 4 \text{ GeV}/c$  and manifest by an enhancement of the  $\Lambda$  yields.

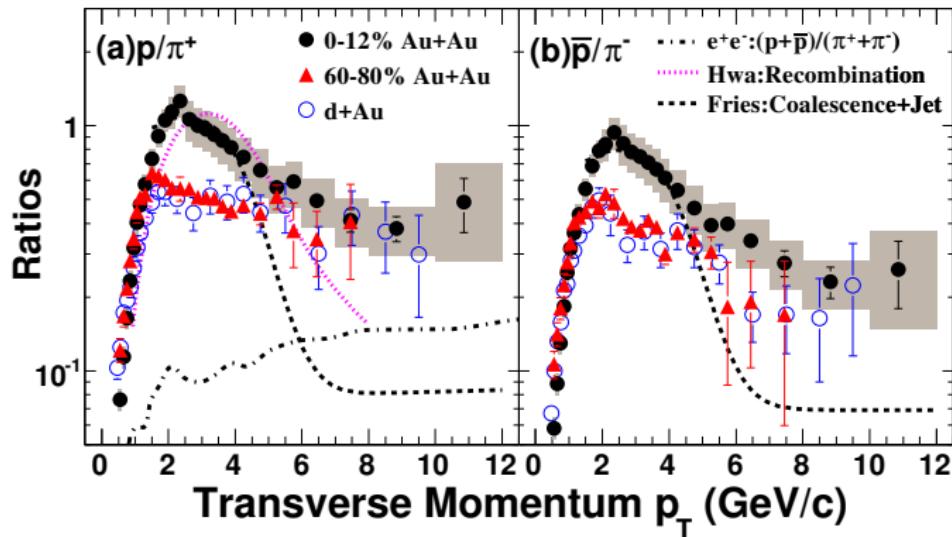

### Outlook

- ▶ Solve the 2011/2010 issue.
- ▶ Comparison with more models (JEWEL).

Thank you for your attention.

$\bar{\Lambda}/\Lambda$ , inclusive, field-

# $V^0$ candidate selection

Cut variable	Value
Daughter tracks	
TPC refit	true
type of production vertex	not kKink
DCA to the primary vertex	$\geq 0.1\text{ cm}$
DCA between daughters	$\leq 1\sigma_{\text{TPC}}$
$ \eta $	$\leq 0.8$
$V^0$ candidate	
reconstruction method	offline
cosine of the pointing angle (CPA)	$\geq 0.998$
radius of the decay vertex	5–100 cm
$ \eta $	$\leq 0.7$
transverse proper lifetime	$\leq 5\tau$
Armenteros–Podolanski cut ( $K_S^0$ )	$p_T^{\text{Arm.}} \geq 0.2  \alpha^{\text{Arm.}} $

# Jet algorithms

A sequential recombination jet finder is defined according to this general scheme:

1.  $\forall i, j : \text{calculate distances } d_{ij} \text{ and } d_{iB}$  (NB  $k_t \equiv p_T$ ):

$$d_{ij} = \min \left( k_{t,i}^{2p}, k_{t,j}^{2p} \right) \frac{\Delta_{ij}^2}{R^2}, \quad \Delta_{ij}^2 = (y_i - y_j)^2 + (\phi_i - \phi_j)^2, \quad d_{iB} = k_{t,i}^{2p}$$

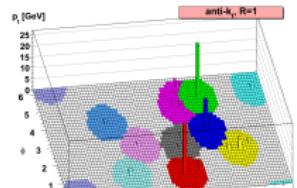

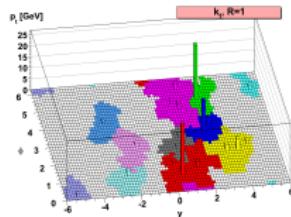

2. Find  $d_{\min}$ :

$$d_{\min} = \min (d_{ij}, d_{iB}) .$$

- If  $\exists i, j : d_{\min} = d_{ij}$ , merge particles  $i$  and  $j$  into a single particle and combine their momenta.
- If  $\exists i : d_{\min} = d_{iB}$ , declare particle  $i$  to be a final jet and remove it from the list.

These steps are repeated until no particles are left.

$$p = \begin{cases} 1 & k_t \text{ (background estimation)} \\ 0 & \text{Cambridge/Aachen} \\ -1 & \text{anti-}k_t \text{ (signal jets)} \end{cases}$$

# Background in Pb–Pb

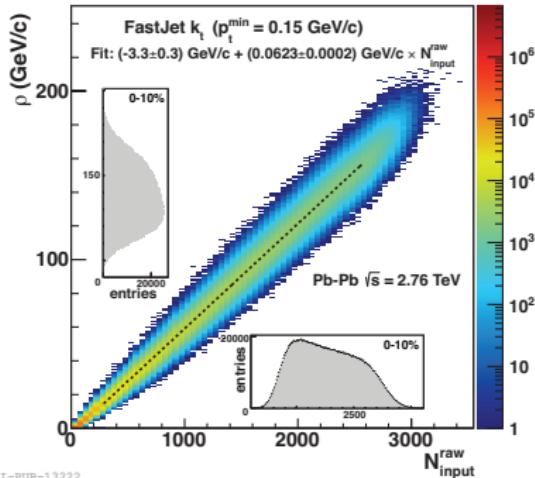

Production of soft particles by underlying-event processes.

average background density  $\rho$ :

- ▶  $k_t$  jets w/o 2 hardest

each event:  $\rho = \text{median} \left\{ p_T^{\text{jet}} / A_{\text{jet}} \right\}$

each jet:  $p_{T,\text{jet}}^{\text{corrected}} = p_{T,\text{jet}}^{\text{raw}} - \rho A_{\text{jet}}$

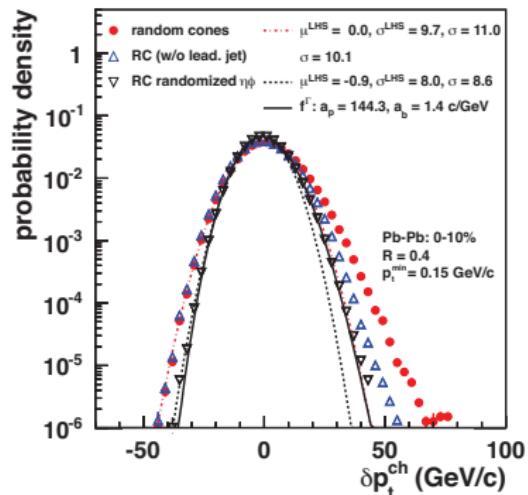

ALICE-PUB-13222

ALICE, JHEP 1203 (2012) 053

$\rho$  anisotropy in events (fluctuations):

- ▶  $\delta p_T = p_{T,\text{probe}}^{\text{raw}} - \rho A_{\text{probe}}$
- ▶ response matrix → deconvolution

ALICE-PUB-13226

ibid.

## Scaling of the reconstruction efficiency

- ▶  $\epsilon$  — reconstruction efficiency of inclusive particles
- ▶  $\epsilon_s$  — reconstruction efficiency of particles of interest (scaled  $\epsilon$ )
- ▶  $a_s$  — yield of associated particles of interest
- ▶  $g_s$  — yield of generated particles of interest
- ▶  $m$  — uncorrected yield of measured particles (candidates) of interest
- ▶  $t$  — yield of true (corrected) particles of interest
- ▶  $P$  — signal purity

Signal extraction in JC, UE (assume that  $P_{\text{inclusive}}(p_T^{\nu^0}, \eta_{\nu^0})$  is the same as for  $\nu^0$ 's of interest):

$$m(p_T^{\nu^0}, \eta_{\nu^0}) = m_{\text{raw}}(p_T^{\nu^0}, \eta_{\nu^0})|_{\text{peak region}} \cdot P_{\text{inclusive}}(p_T^{\nu^0}, \eta_{\nu^0})|_{\text{peak region}}$$

Efficiency calculation:

$$a_s \equiv m, \quad \sigma_{a_s} \equiv 0, \quad g_s = a_s/\epsilon$$

$$\frac{1}{\epsilon_s(p_T^{\nu^0})} = \frac{\sum_{\eta_{\nu^0 i}} g_s(\eta_{\nu^0 i}, p_T^{\nu^0})}{\sum_{\eta_{\nu^0 j}} a_s(\eta_{\nu^0 j}, p_T^{\nu^0})} = \sum_{\eta_{\nu^0 i}} \frac{a_s(\eta_{\nu^0 i}, p_T^{\nu^0})}{\sum_{\eta_{\nu^0 j}} a_s(\eta_{\nu^0 j}, p_T^{\nu^0})} \frac{1}{\epsilon(\eta_{\nu^0 i}, p_T^{\nu^0})}$$

Spectra correction:

$$t = m/\epsilon_s$$
