

Picosec Micromegas for the Muon Collider Detector

D. Fiorina – INFN Pavia
On behalf of the Muon Collider Collaboration

1. Introduction to the Muon Collider

- Requirement for Muon timing in Muon collider

2. Test Beam results

- Photoelectrons measurement
- Timing measurements

3. Rate capability (preliminary results)

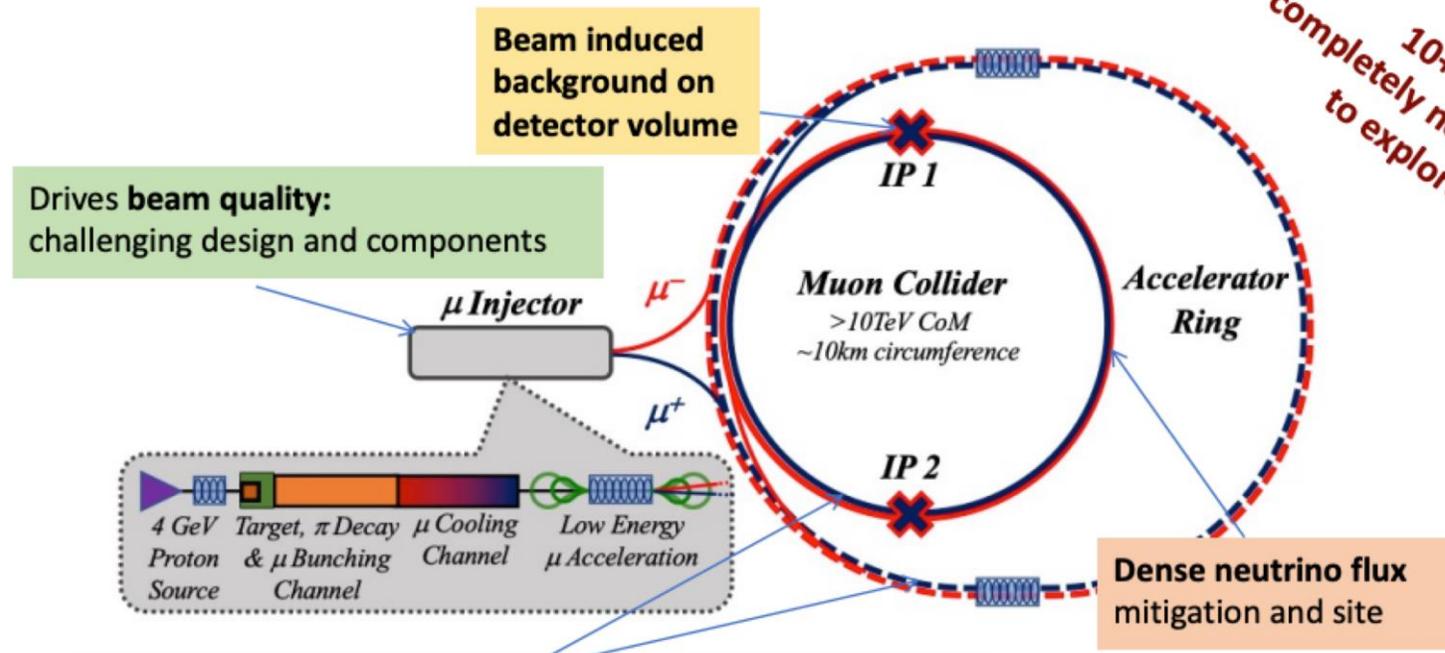

4. Eco-friendly gas (preliminary results)

International Design Study facility

Proton driver production as baseline

- Focus on two energy ranges:
 - 3 TeV technology ready for construction in 10-20 years
 - 10+ TeV with more advanced technology

10+ TeV completely new regime to explore!

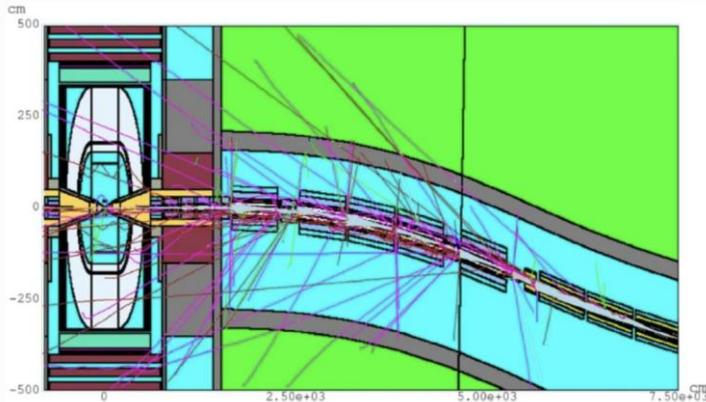

Cost and power consumption drivers, limit energy reach e.g. 30 km accelerator for 10/14 TeV, 10/14 km collider ring

- Simulations available for $\sqrt{s}=1.5\text{TeV}$
- Production ongoing for $\sqrt{s}=3\text{TeV}$

Design phase of the Muon Collider Detector

For the muon endcaps, a **Muon tracking and timing station** based on **Picosec+MPGD** has been proposed

Shielding from Beam Induced background (from decaying muons) limits the coverage in eta ($\theta > 8^\circ$, $\eta < 2.7$ available)

hadronic calorimeter

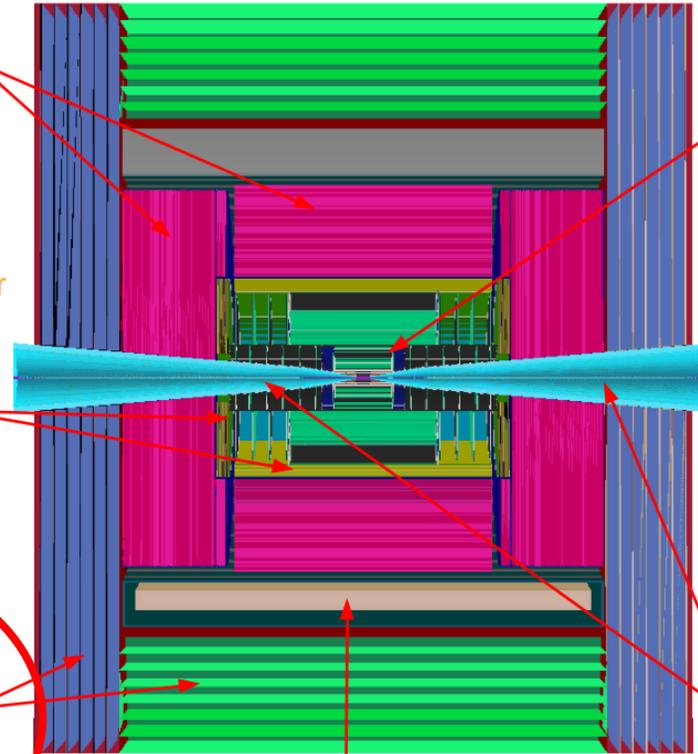

- ◆ 60 layers of 19-mm steel absorber + plastic scintillating tiles;
- ◆ 30x30 mm² cell size;
- ◆ 7.5 λ_I .

electromagnetic calorimeter

- ◆ 40 layers of 1.9-mm W absorber + silicon pad sensors;
- ◆ 5x5 mm² cell granularity;
- ◆ 22 $X_0 + 1 \lambda_I$.

muon detectors

- ◆ 7-barrel, 6-endcap RPC layers interleaved in the magnet's iron yoke;
- ◆ 30x30 mm² cell size.

superconducting solenoid (3.57T)

tracking system

- ◆ **Vertex Detector:**
 - double-sensor layers (4 barrel cylinders and 4+4 endcap disks);
 - 25x25 μm^2 pixel Si sensors.
- ◆ **Inner Tracker:**
 - 3 barrel layers and 7+7 endcap disks;
 - 50 $\mu\text{m} \times 1 \text{mm}$ macro-pixel Si sensors.
- ◆ **Outer Tracker:**
 - 3 barrel layers and 4+4 endcap disks;
 - 50 $\mu\text{m} \times 10 \text{mm}$ micro-strip Si sensors.

shielding nozzles

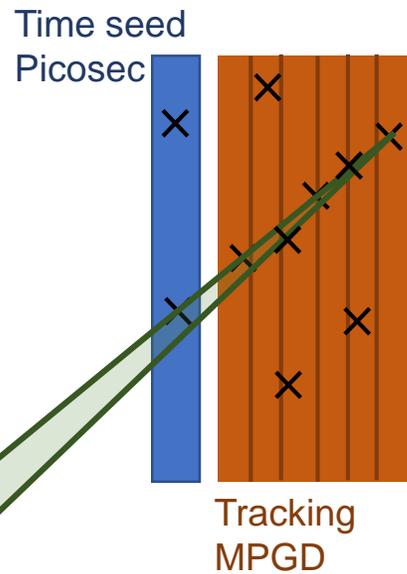

- ◆ Tungsten cones + borated polyethylene cladding.

Muon endcap

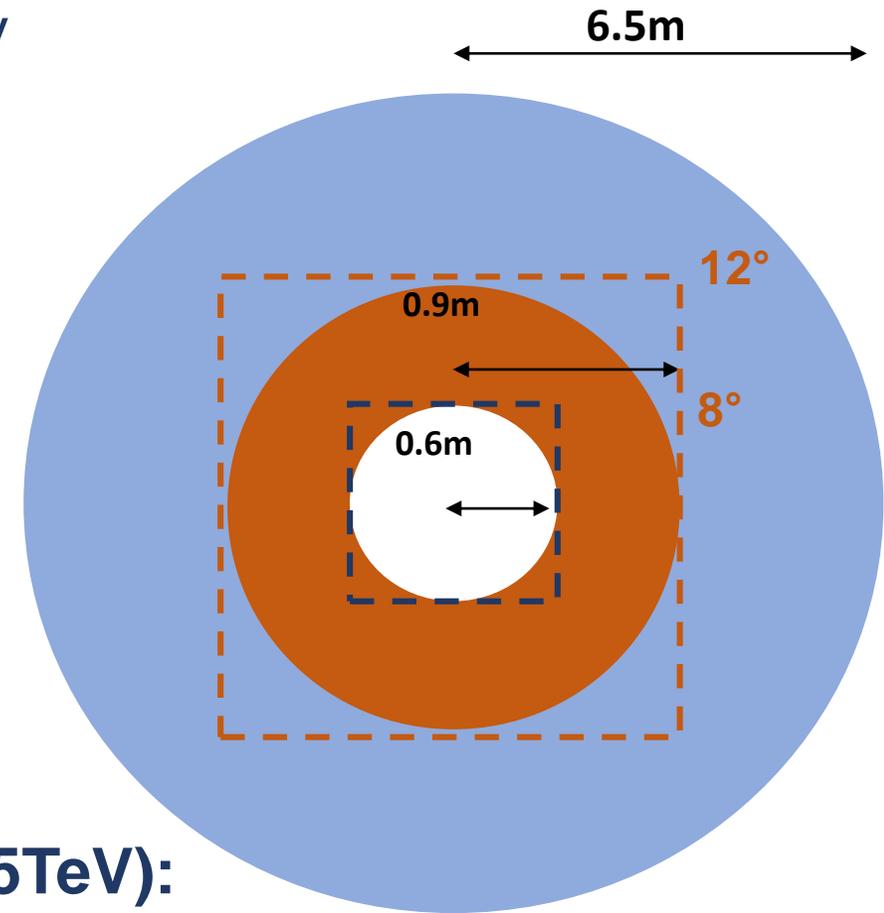

Out-to-In muon tracking approach currently under study

Resolve muon in the muon system to close the track in the tracker system
reducing the combinatory background

Time resolution ~100ps

Operation in a heavily ionising particle environment

Endcap – not in scale

Rate capability ($\sqrt{s}=1.5\text{TeV}$):

- **60 kHz/cm²** $8^\circ < \theta < 12^\circ$
- 2 kHz/cm² $\theta > 12^\circ$

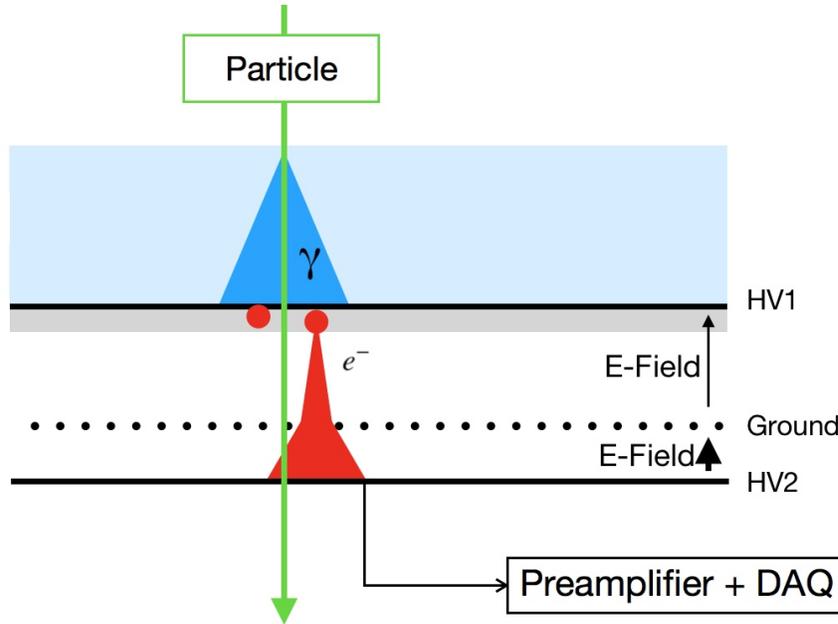

Picosec Micromegas

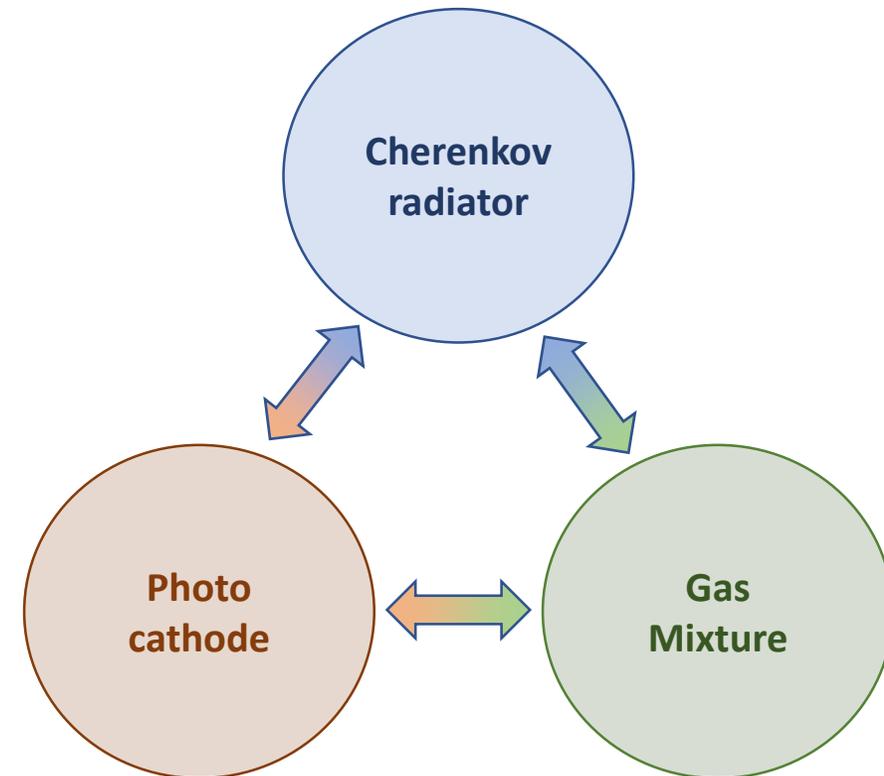

Gas Mixture:

Ne/C₂H₆/CF₄
80/10/10

Cherenkov Radiator	MgF ₂ 3mm
Photocathode	CsI 18nm
Drift	200μm
Amplification	128μm

- 1. Look at Cherenkov, not the ionisation**
Photo-electrons created promptly with the MIP passage
- 2. Remove the 'drift' gap and start the avalanche as soon as possible**
Avalanche propagate faster

Cherenkov radiator MgF2:

- Optimal UV transparency, high cost, no technology for large windows, fragile

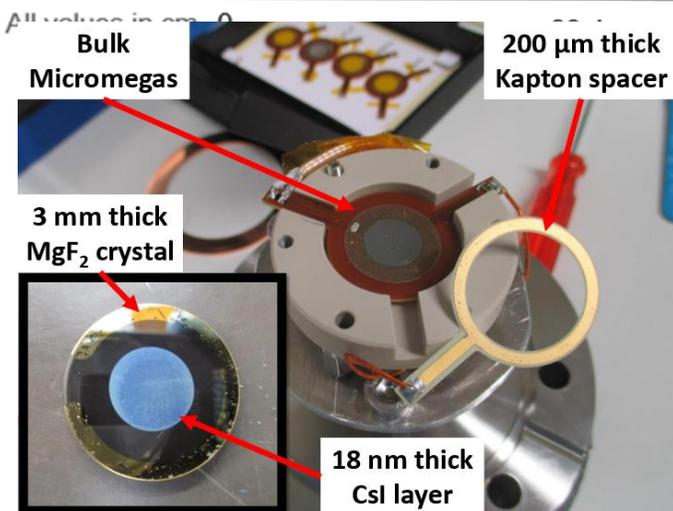

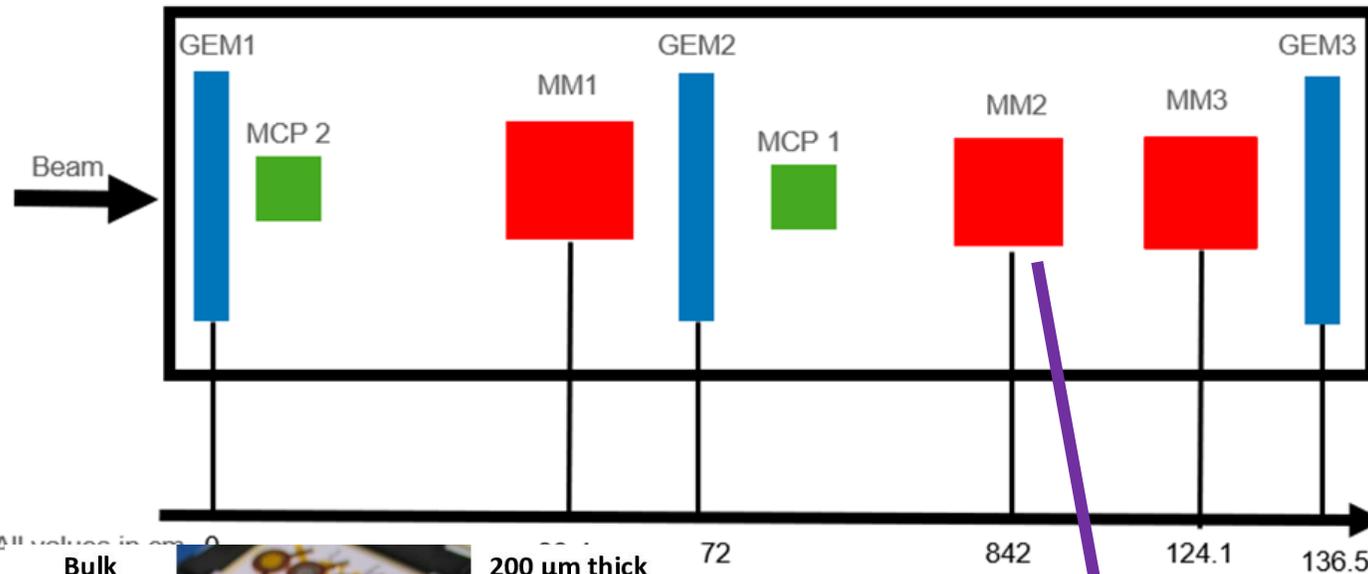

Photocathode CsI:

- Best UV QE, radiation damage, Hygroscopic

Gas Ne/C₂H₆/CF₄:

- High quenching, high-cost, non-eco-friendly

MCP for time reference $\sigma_t \approx 5ps$

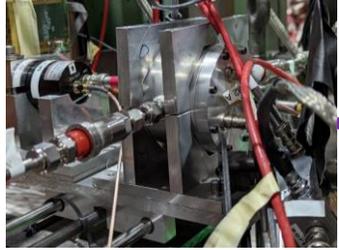

Test beam, 19Oct-1Nov 2022

- Profited of the RD51 GEM-based tracker
- Participated to full RD51 R&D campaign
 - First beam time with a **dedicated detector for muon collider R&D**

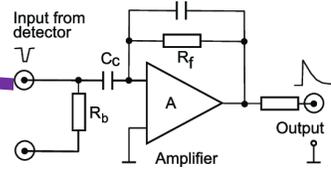

Single-channel:

- Test the detector operation on the beam
- Measure different **radiator+photocathode combination yield** (photoelectrons/MIP) and compare
- Measure **time resolutions** with different **radiator+photocathode** combination
- Comparison between **non-resistive** MM (amplification 150um) and **resistive** MM (amplification 128um)

Single-channel setup - Photoelectrons/MIP measurement-

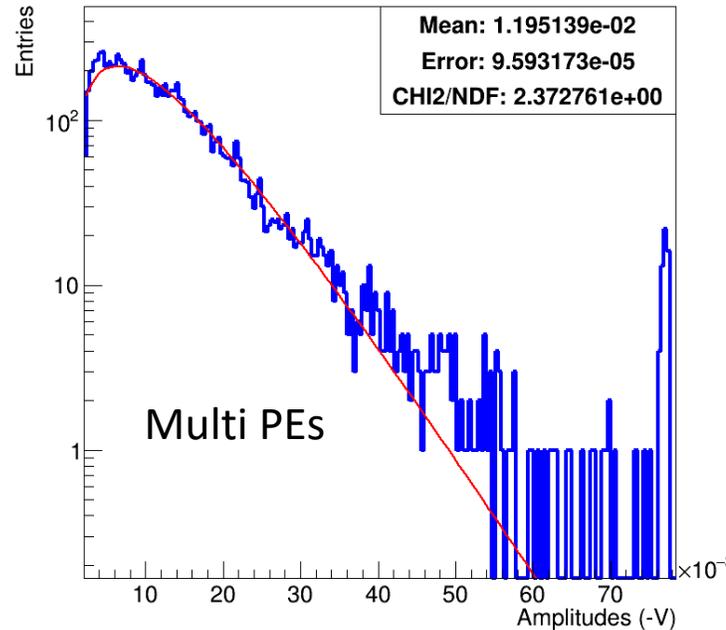

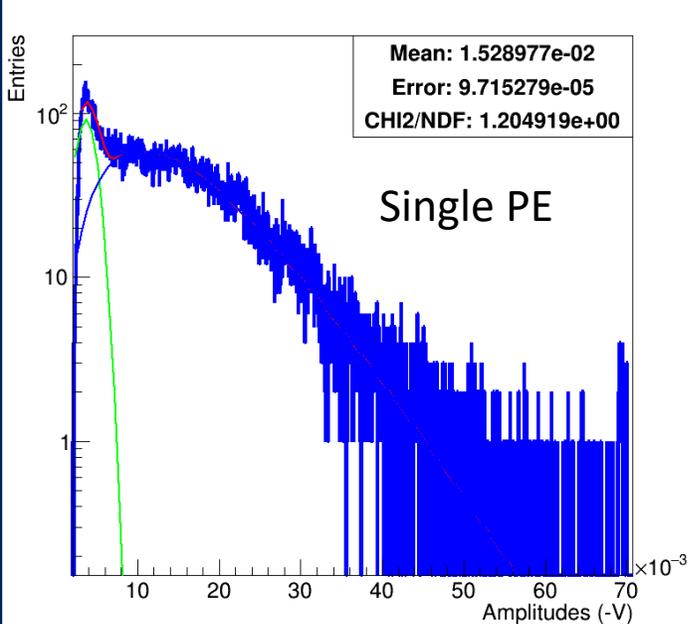

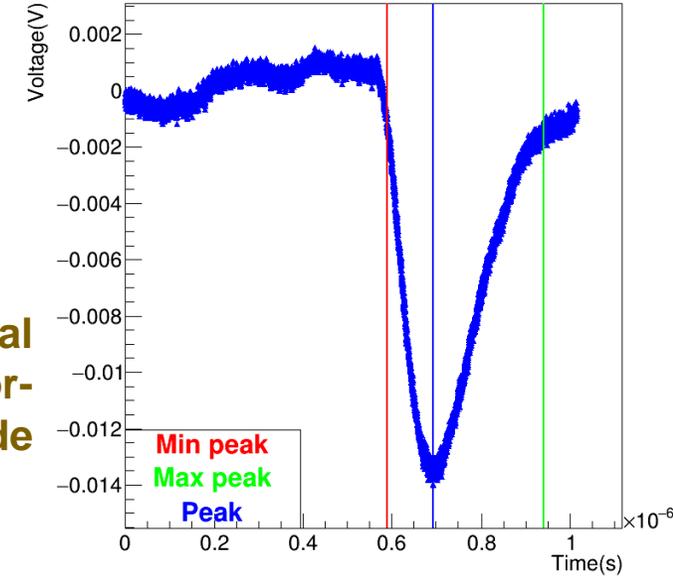

Charge amplifier

Waveform saved for processing

- Charge spectrum with UV LED → single photoelectron spectrum
- Charge spectrum with beam → photoelectrons from beam spectrum
 - Geometrical cut essential to select only fully contained Cherenkov cones

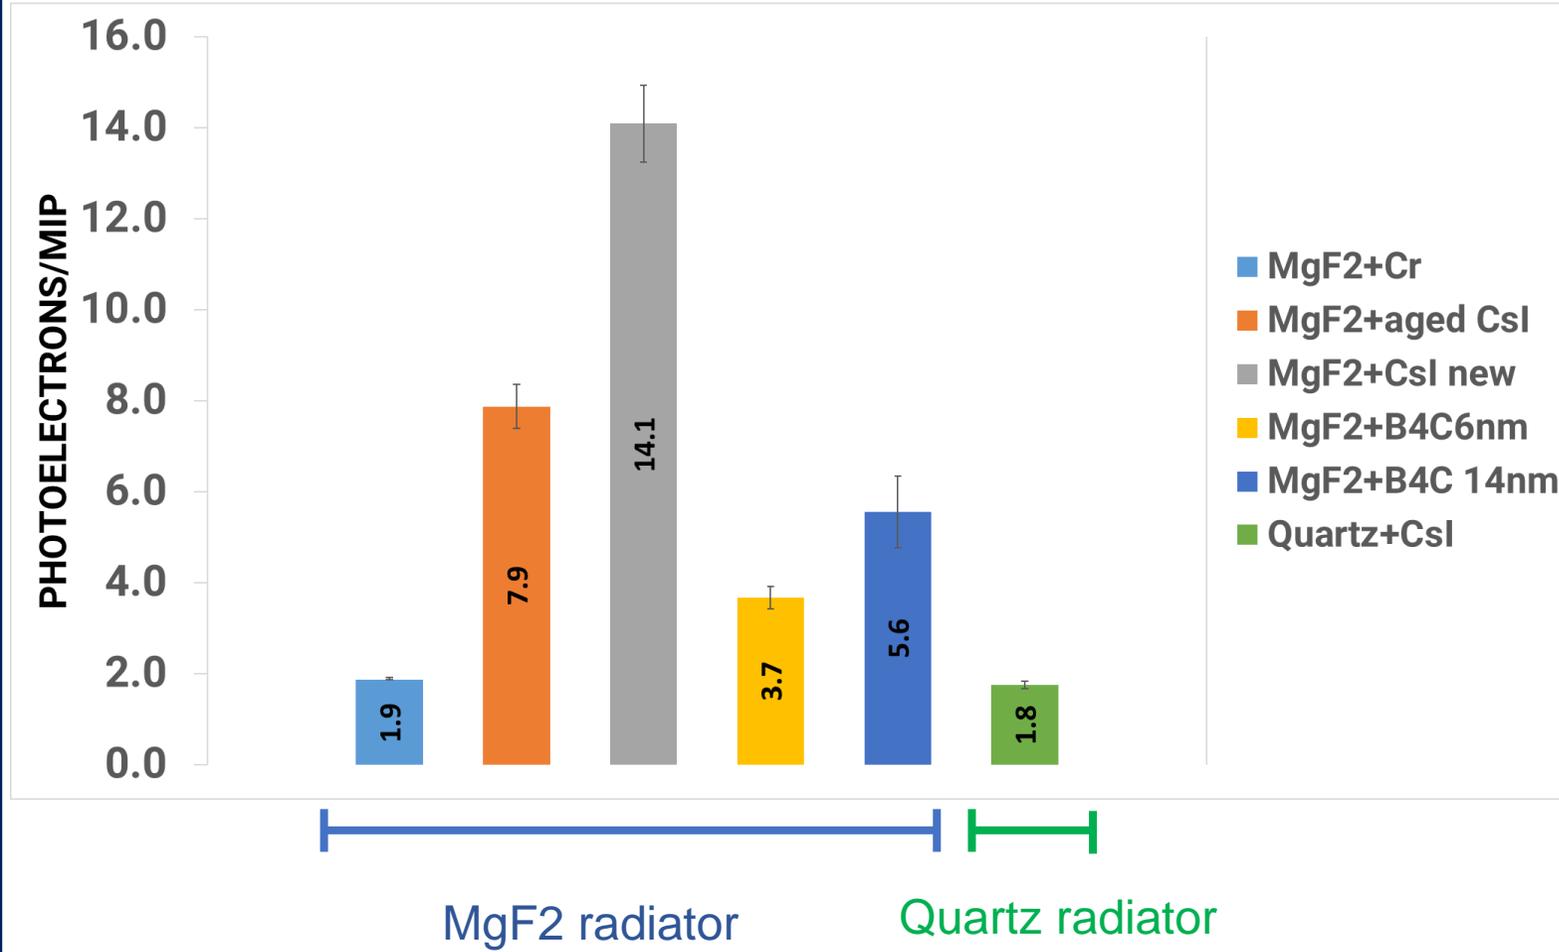

**Integral of the signal
-or-
Just the amplitude**

Polya function (negative binomial)
Describe well the gain fluctuation when
the primary charges are low

$$p(x) = \frac{(1 + \theta)^{1+\theta}}{\Gamma(1 + \theta)} \frac{x^\theta}{\bar{x}} e^{-\frac{(1+\theta)x}{\bar{x}}}$$

Photoelectrons per Muon

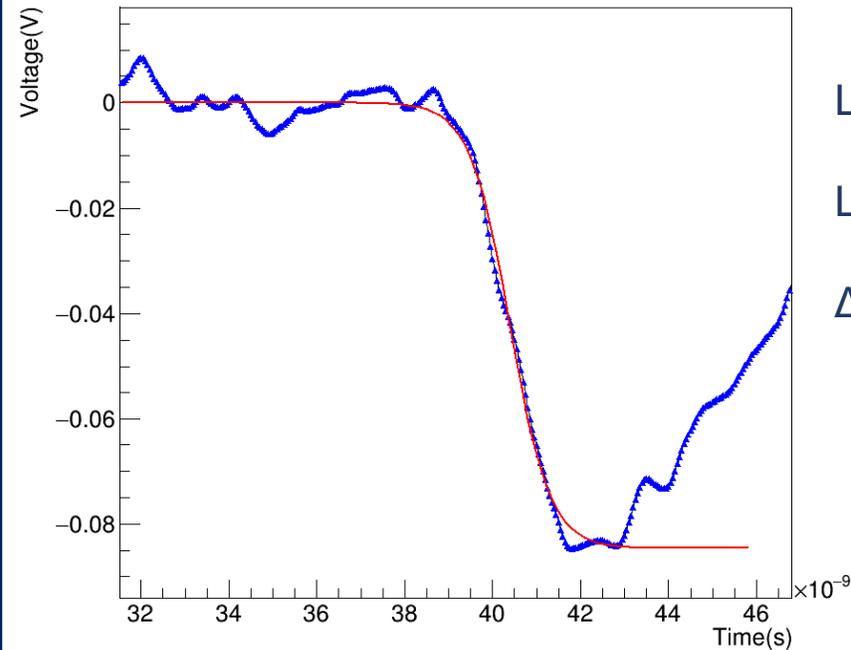

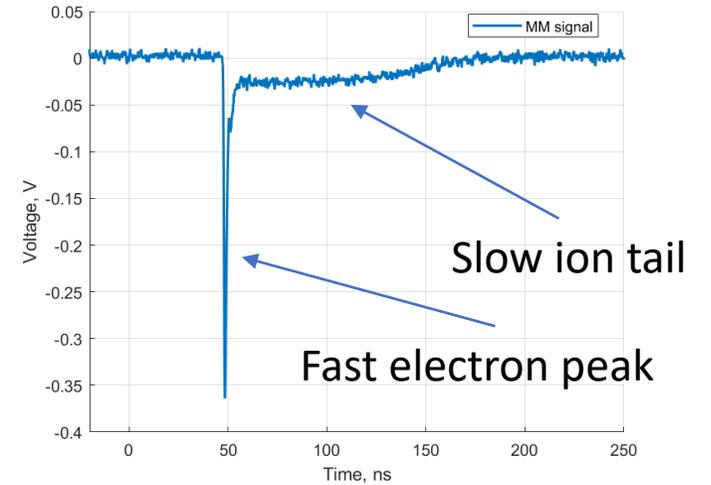

The ratio among the mean amplitudes gives the average number of photoelectrons per incoming muon.

- We don't know precisely the amount of aging of the CsI photocathode in orange, but it was handled in the air multiple times (collected humidity damage). **CsI is prone to degradation if exposed to humidity and heavy ion bombardment**
- **Quartz is not a good radiator.** Its yield is an order of magnitude lower than MgF2. May create some inefficiencies
- **B4C is very promising** (12nm demonstrated the best performance https://indico.cern.ch/event/1219224/contributions/5130512/attachments/2565710/4423222/Marta_Lisowska_-_PICOSEC_Micromegas_-_MPGD2022.pdf). Moreover is resistive (spark protection) and easy to handle.

Single-channel setup -Timing measurement-

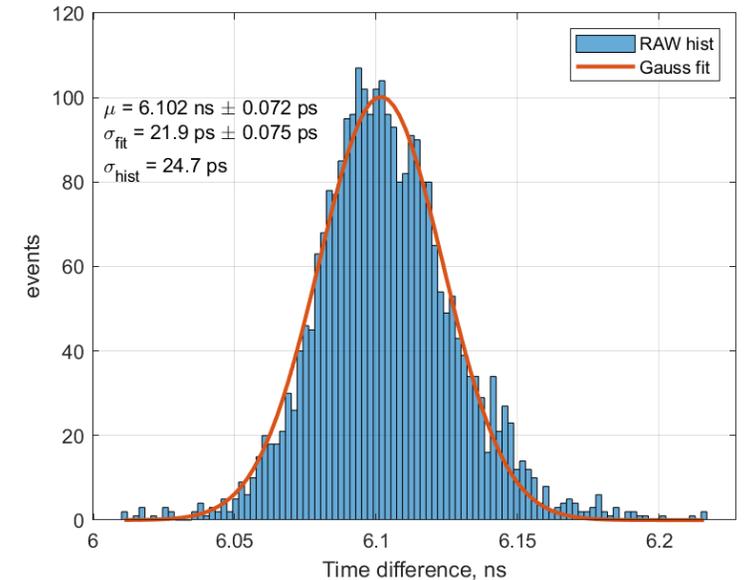

Current amplifier
To preserve the rising edge!

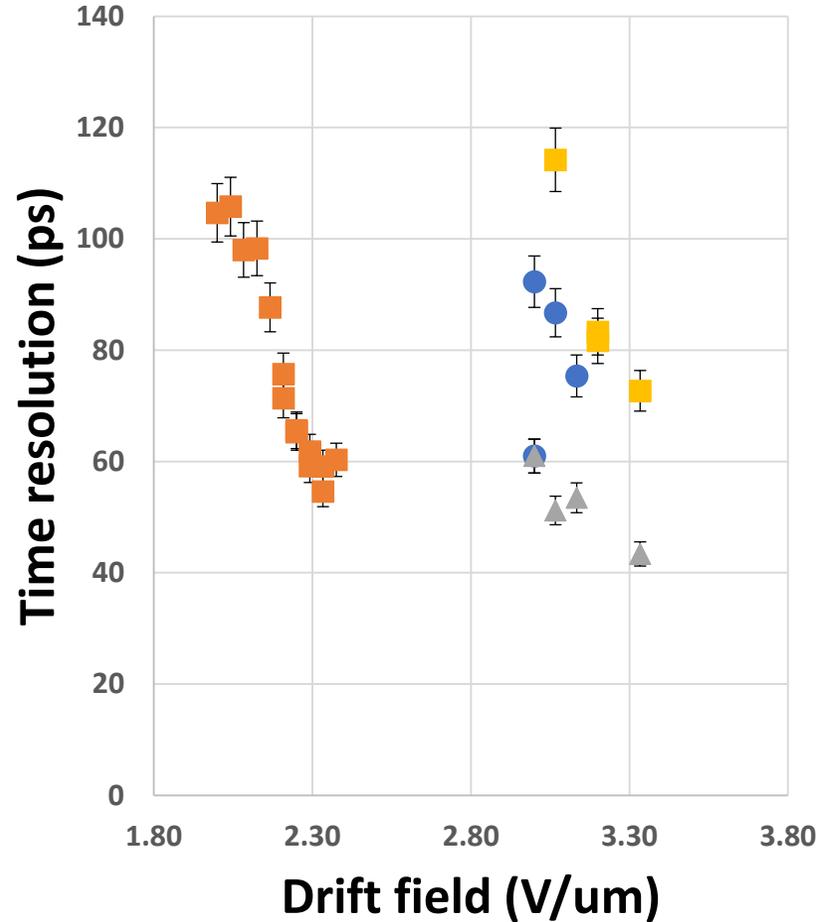

Logistic function fit on Picosec signal
→ CFD on fit → Signal Arrival Time
Logistic function fit on MCP signal
→ CFD on fit → Signal Arrival Time
 Δt between the SATs gives the time resolution!

The geometrical cut on the fully contained cones is fundamental also in timing.

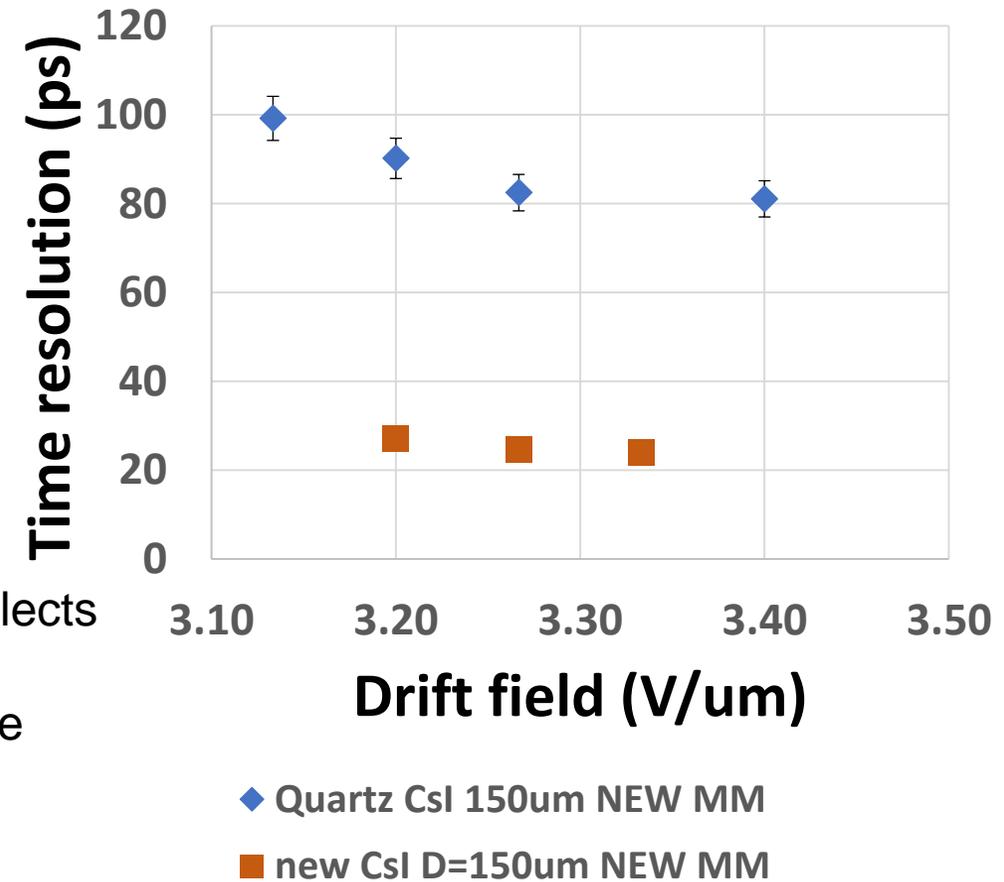

Timing Results

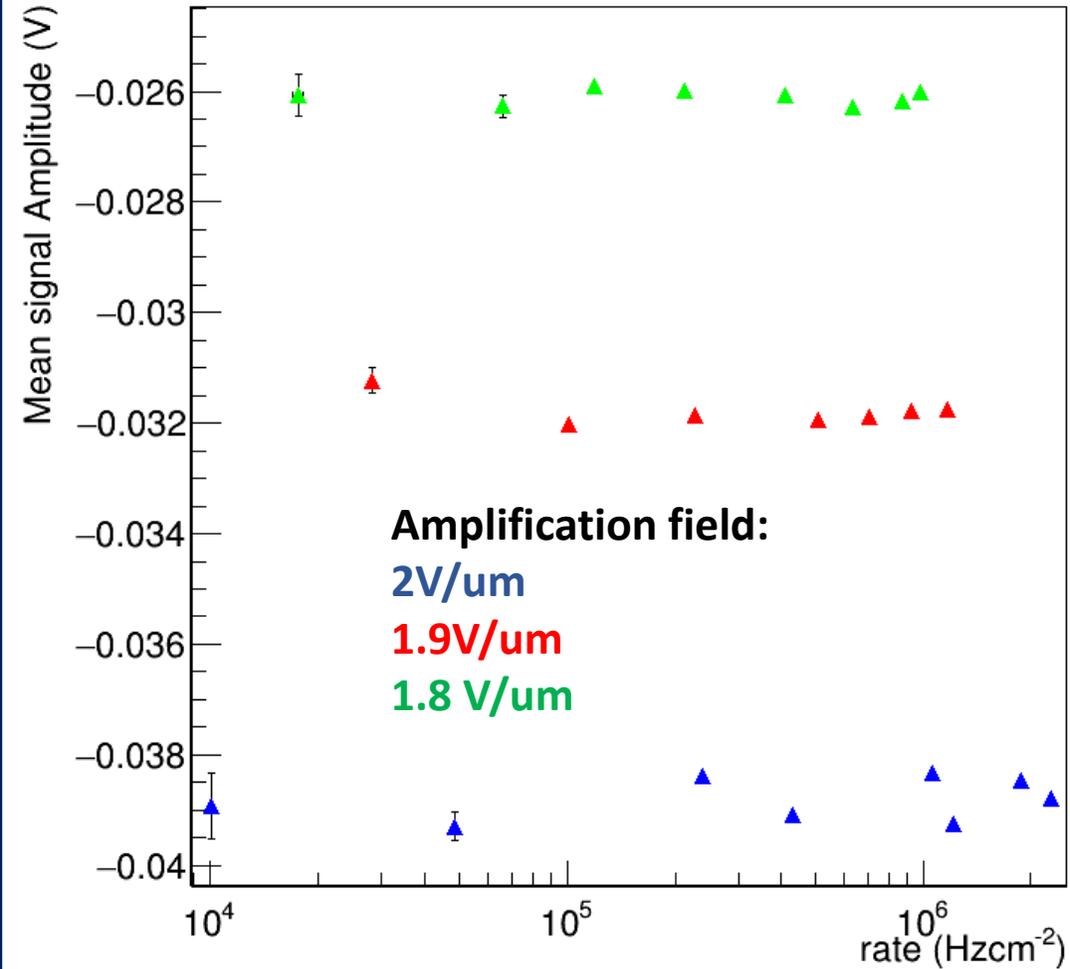

■ Aged CsI D=240um
● B4C 14nm D=150um
▲ new CsI D=150um
■ B4C 6nm D=150um
 ← non-resistive MM 150um
 1.84 V/um
 Resistive MM 128um
 2.15kV/um →

- The timing performance reflects the number of PEs/MIP
- All the combinations may be suitable for Muon Collider application (<100ps)

Mean signal Amplitude (V) vs rate (Hzcm⁻²)

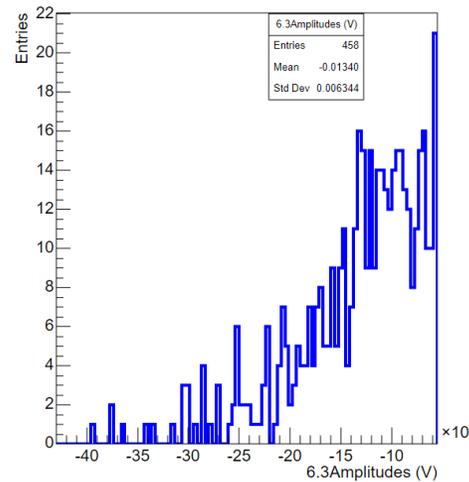

Irradiation with UV LED to generate **single-photoelectrons** signals

- CsI photocathode
- Counts signals and measures the average amplitudes
- Drift field: 3.13 V/um

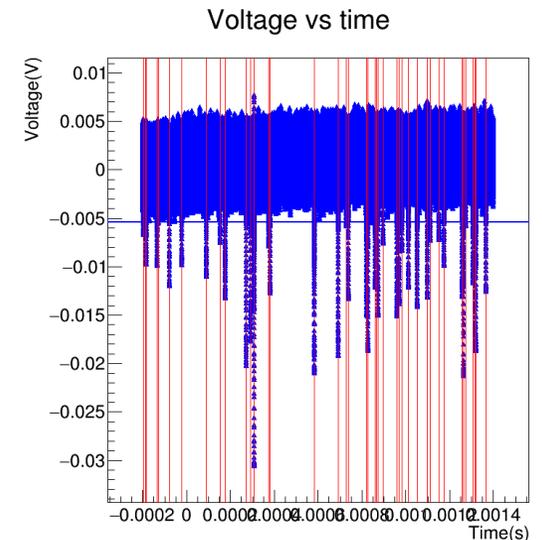

Detector performance stays **stable up to 2MHz/cm²** for single-photoelectron

- One can roughly scale a factor of 10 for Muons
- We can go higher with the rate, but we have to fight against CsI degradation

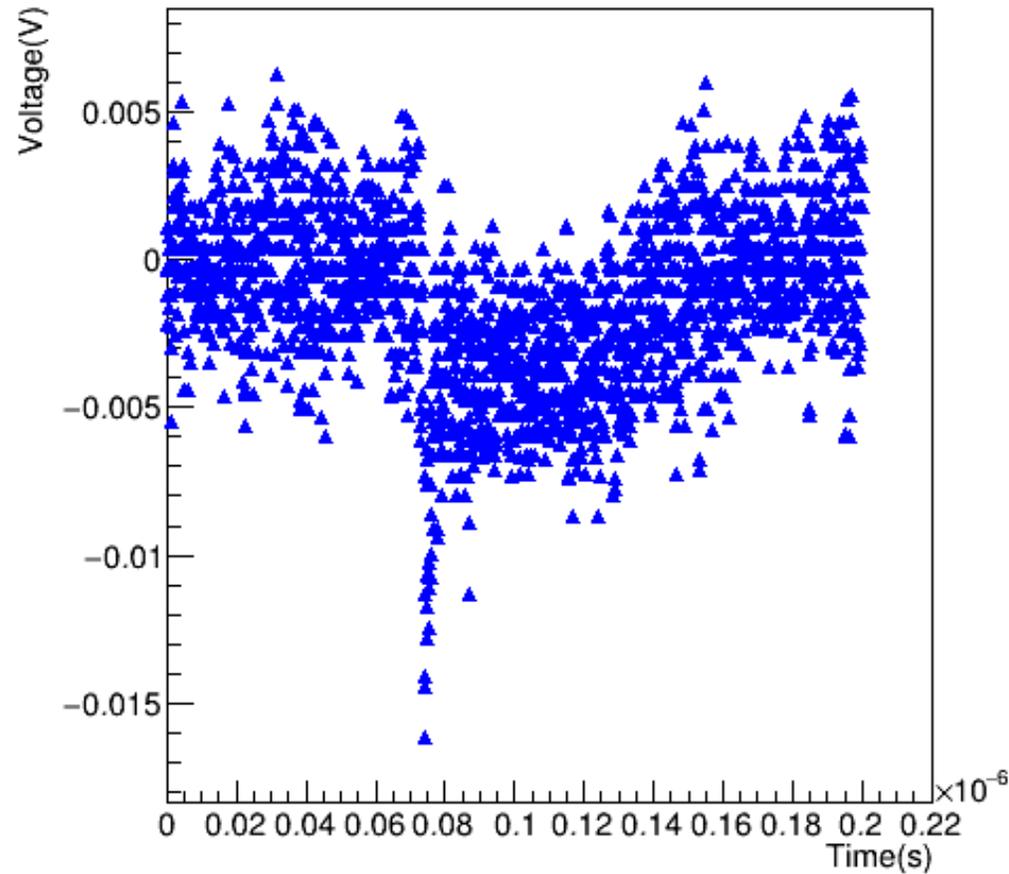

← Example of an amplitude spectrum

Example of 1.6ms of acquisition →

DUT_ArCO20

- LED irradiation → single Photoelectrons signals
- **Gas: Ar/CO2 93/7**
- Drift: 150um, Amplification: 150um
- Drift: 380V, Amplification 480V (max voltages achievable with such mixture)

Many of the signals do not present the expected electron-peak/ion-tail ratio

- Multiple signals on the same rising edge
- Probably caused by some feedback process because of the low quenching gas?
- Any suggestion on that is very welcomed 😊

Conclusions

Muon Collider requirement

- **~100ps** time resolution
- **60kHz/cm²** rate capability
- **Spark and radiation hard** detector
- Scalable technology up to **~m²** (baseline option is to tile a large surface with small detectors)

Test Beam results

- All configurations **satisfied the ~100ps** time resolution
- **Quartz+Csl and MgF2+Chromium may lead to inefficiencies** because of the low number of photoelectrons
- **Csl** is the best photocathode but can be **easily damaged** by ion bombardment and humidity
- **B4C** is a very **promising** candidate (resistive and easy to handle)
 - Not suitable for Muon Collider because of neutrons, but **DLC** should have a similar performance

Rate capability

- Detector response to single photoelectrons stable **up to 2MHz/cm²**
- Operational limit will be tested soon!

Eco-friendly gas

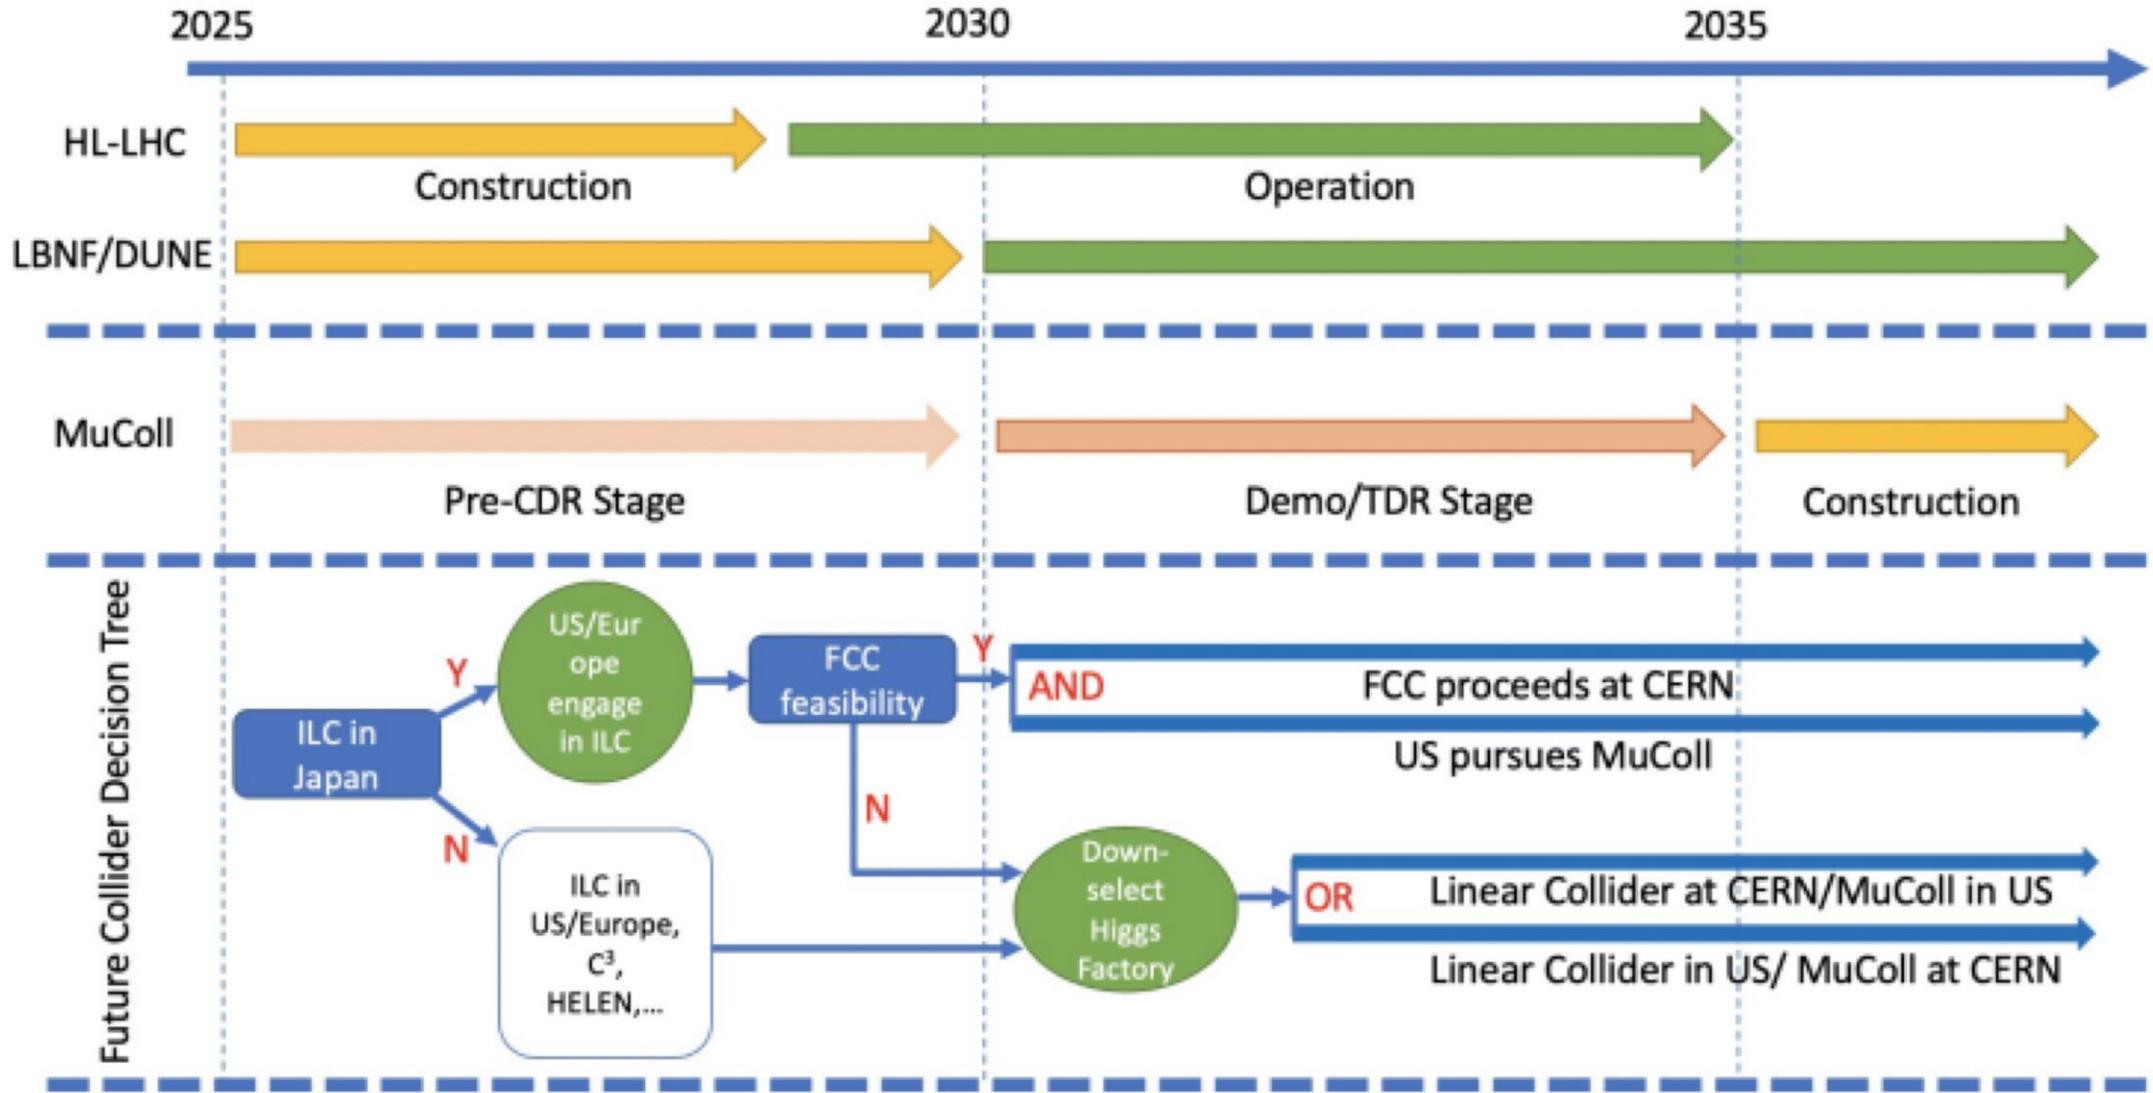

- Ar/CO₂ (93/7) seems to have a too-small quenching factor for good performance in a single photoelectron case
- New gases will be tested in Pavia (Ne, Ar, C₂H₆, C₄H₁₀, R1234ze...)

DRD1 transition:

- Pavia group is the 'watcher' in the Muon Collider Collaboration for the new DRD1
- Expression of interest in RPC, straw tubes and MPGDs (Picosec but not only)

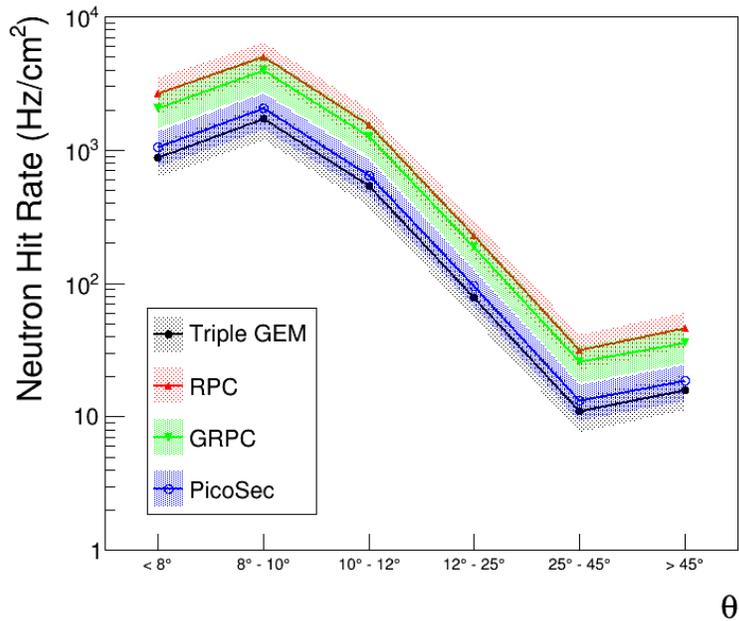

BACKUP

Timeline

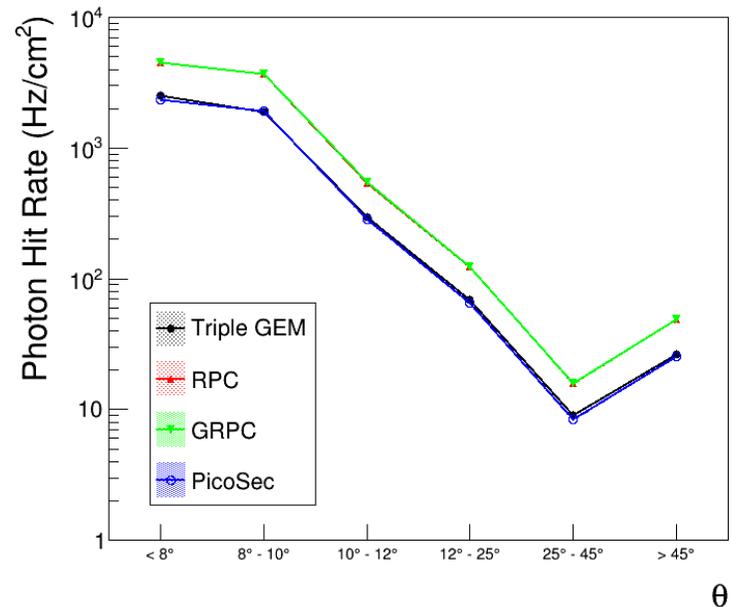

Simulation background

Muon Collider 1.5 TeV - Neutron Hit Rate vs θ

Muon Collider 1.5 TeV - Photon Hit Rate vs θ

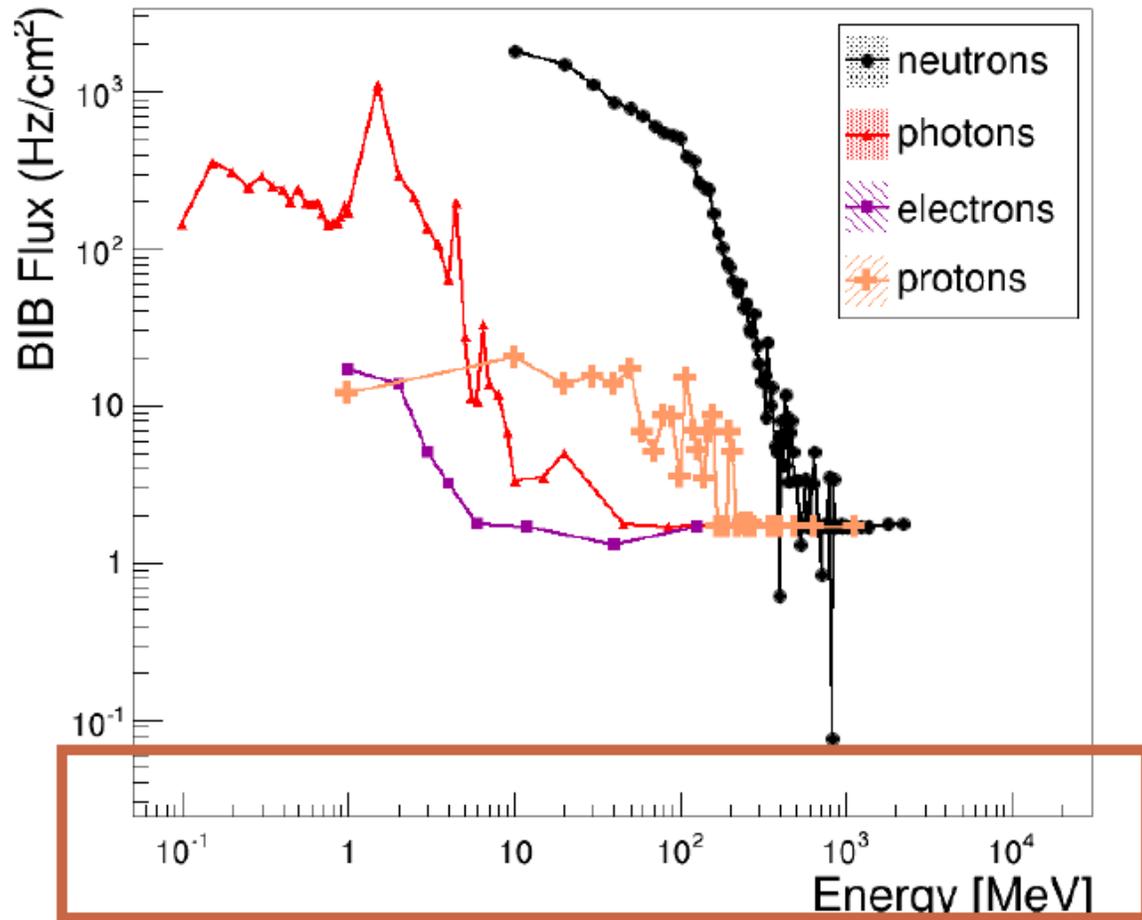

BIB particles flux [Hz/cm²] in different regions (bunch crossing time 10 μ s):

Particle	Endcap ($\theta > 12^\circ$)	Endcap ($8^\circ < \theta < 12^\circ$)	Endcap ($\theta < 8^\circ$)	Barrel
neutrons	$1.2 \cdot 10^3$	$5 \cdot 10^4$	$1.2 \cdot 10^6$	$1.4 \cdot 10^2$
protons	16	$3 \cdot 10^2$	$2.4 \cdot 10^4$	----
photons	$6.2 \cdot 10^2$	$1 \cdot 10^4$	$7.2 \cdot 10^5$	5
e+ e-	3	$3.3 \cdot 10^2$	$5 \cdot 10^3$	< 1
$\mu+$ $\mu-$	3	$3.7 \cdot 10^2$	$1.2 \cdot 10^4$	----
pions, kaons	< 1	70	$1 \cdot 10^3$	----
Total	$\approx 2 \text{ kHz/cm}^2$	$\approx 60 \text{ kHz/cm}^2$	$\approx 2 \text{ MHz/cm}^2$	$\approx 200 \text{ Hz/cm}^2$

- Background interaction with the detector was simulated in Geant4
- Convolved with the response of different gaseous detector technologies (hit when a charged particle is found in the drift gap)
- Simulated PicoSec: 3mm MgF2 radiator, 18nm CsI photocathode, 200um drift gap
- **PicoSec can potentially operate in high-rate environments and give timing information with higher precision wrt other technologies**

BIB spectrum

BIB Energy distribution - Entire Endcap

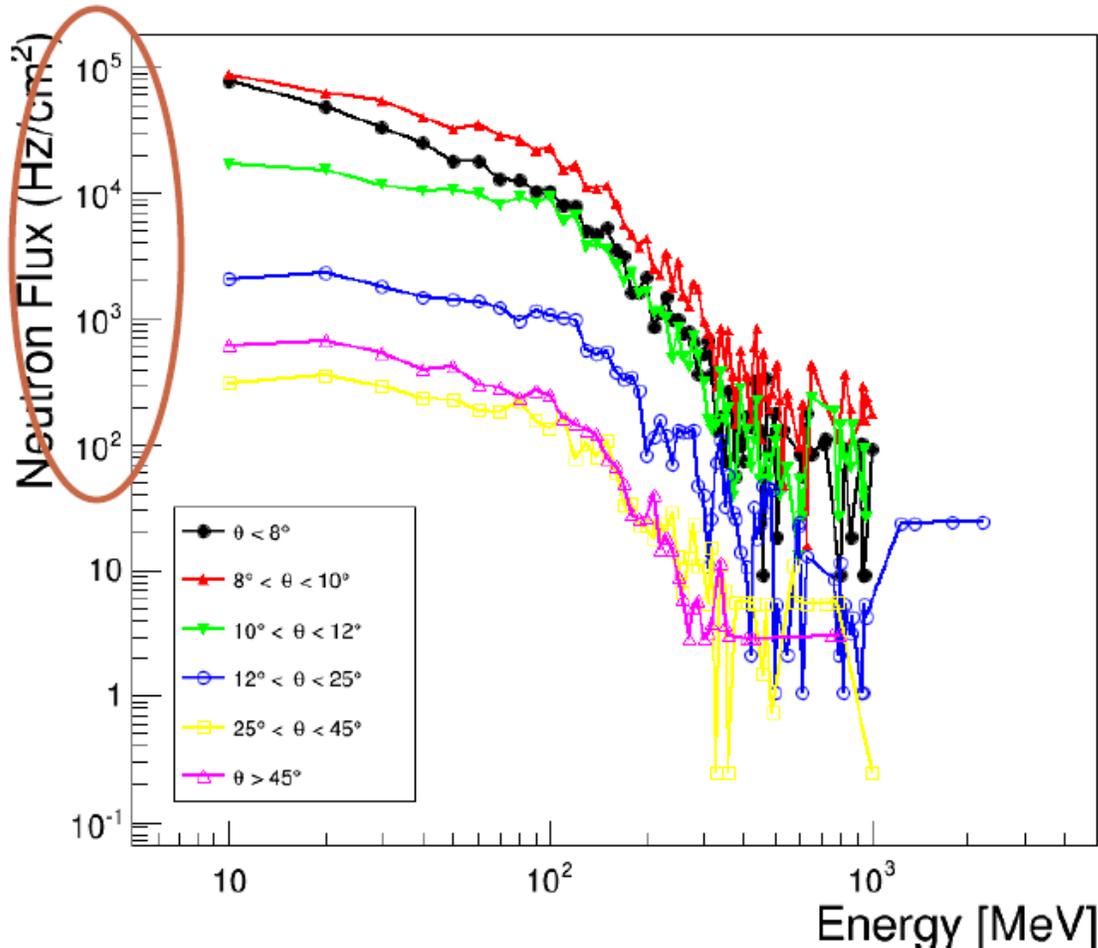

$$f(E) = \frac{p(E) \times BX^{-1}}{A}$$

where

- $p(E)$ = number of particles of a given type and energy reaching the muon system in a BX
- BX^{-1} = number of BX/s (10^5)
- A = considered area

This plot shows the flux on the entire endcap – not to be used to evaluate the actual fluxes on the detectors – but it gives us an overview of particle types and energy ranges.

BIB Energy distribution - Neutrons vs θ

We have divided the endcap region in six sub-regions based on θ (or r):

- In the inner regions, the neutron flux is almost 3 orders of magnitude higher than in the outer regions
- The energy goes from few MeV up to 2.5 GeV \rightarrow *is there any cut on the lower energies?*
- The highest fluxes are for energies below 100 MeV

Selection of detectors for MIP timing

*estimated from pad size
**from real operation

Picosec potential:

- High rate capability wrt MRPC
- Low cost wrt to LGAD

R&D Plan: Cherenkov Radiator

Broken MgF₂ crystal

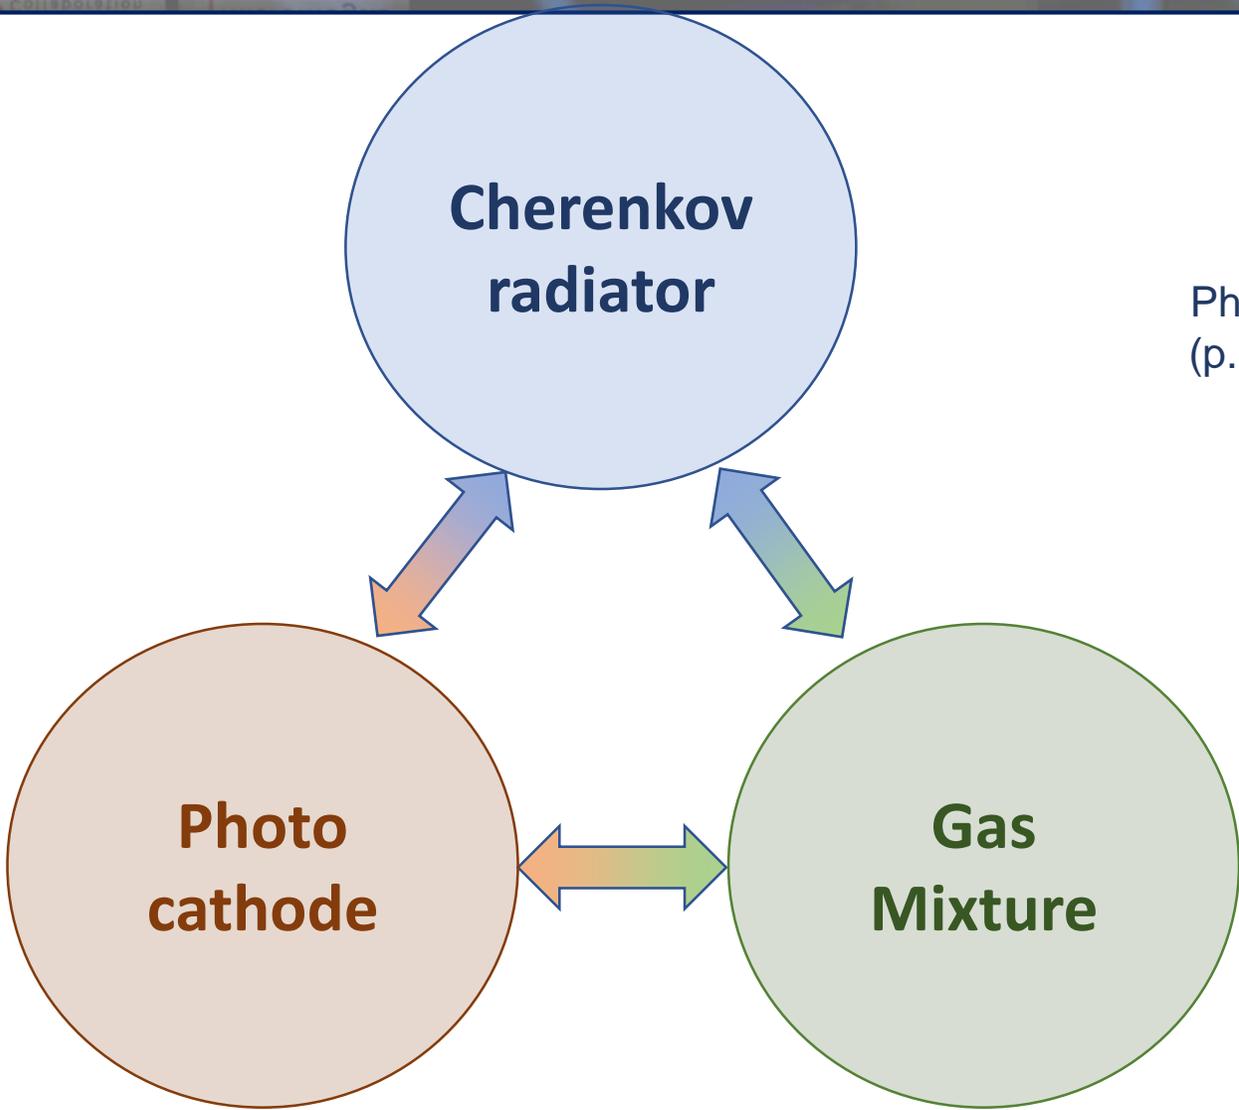

Cherenkov radiator – Baseline MgF₂

- High UV transparency (>120nm)
- Fragile
- High cost (12€/cm²)
- No technology for large areas (100cm² max)

Quartz (5€/cm², >180um)

Sapphire (6€/cm², hard, large area, >170um)

other F-based crystals have to be studied!

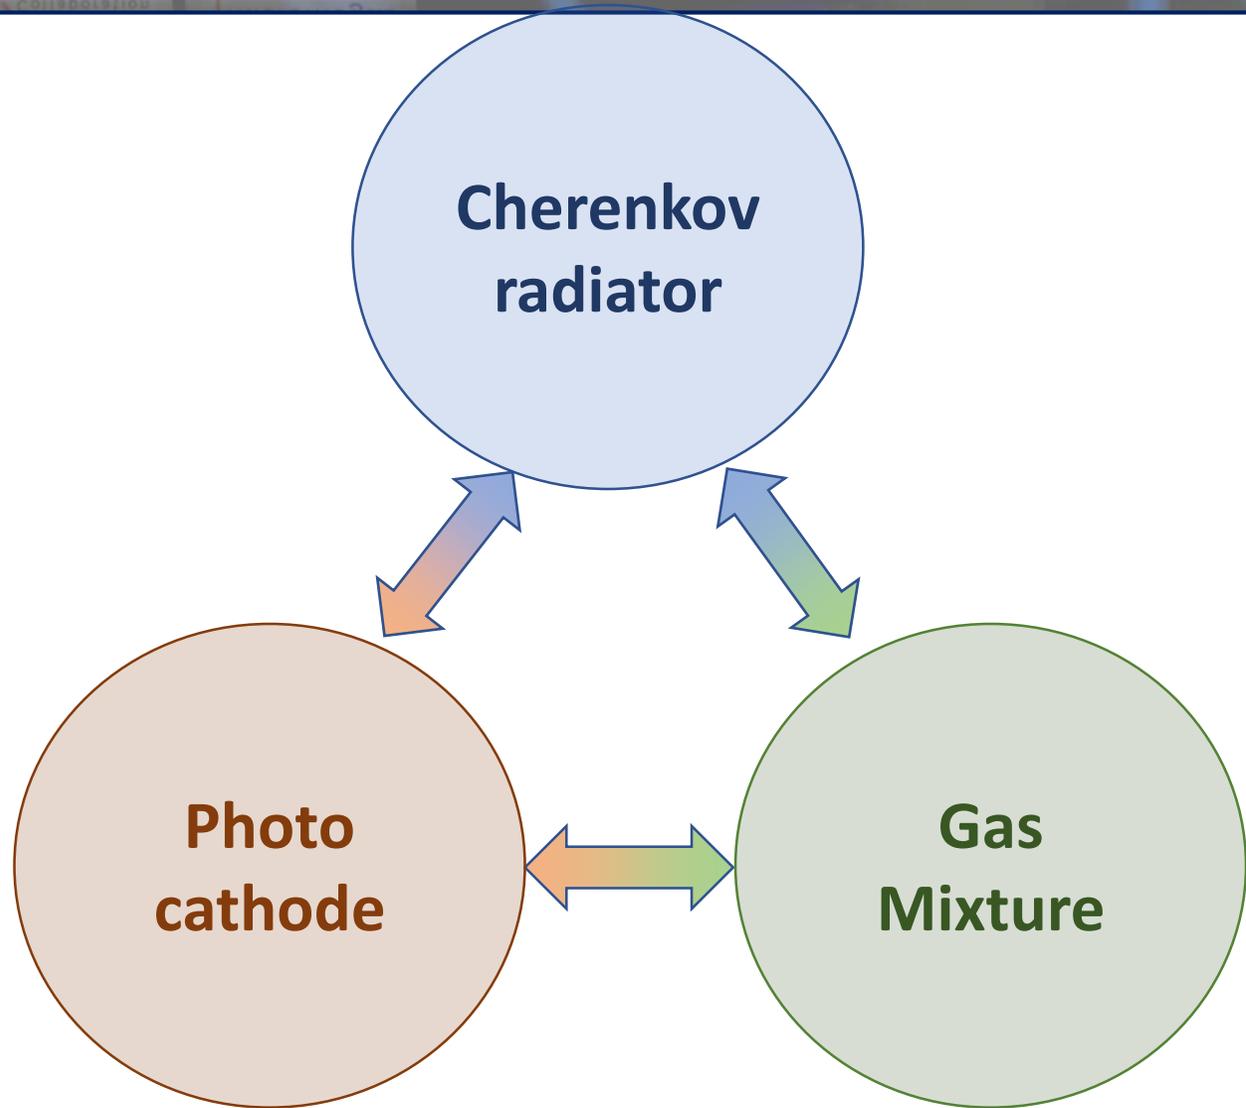

Photoelectrons generated per MIP (p.e./MIP) with 3mm MgF₂ radiator

Photocathode – Baseline CsI

- High quantum efficiency to UV (≈ 10 p.e./MIP)
- Easy to coat by Chemical Vapour Deposition
- Hygroscopic (sealed operation, dry gas)
- Damage by ion bombardment
- Metallic (Al, Cr, Au...) \rightarrow easy to coat, non-resistive (pro and cons), lower QE (1-2 p.e./MIP)
- Carbon-based (DLC, B4C) \rightarrow dedicated sputtering machine, resistive (pro and cons), lower QE (factor 3-4 p.e./MIP)

Gas Mixture– Baseline Ne/C₂H₆/CF₄

- High gain and discharge quenching (up to $2-3 \times 10^5$)
- High drift velocity ($>5 \text{ cm}/\mu\text{s}$)
- Very costly (Ukraine was the main producer of Ne, CF₄ is heavily taxed for its GWP)
- Not eco-friendly (GWP \approx 740)

C₂H₆ (3k€ bottle, GWP=10.2) can be substituted with other quenchers :

- CO₂ (0.7k€ bottle, GWP=1, small quenching)
- iC₄H₁₀ (1.5k€ bottle, GWP=3, good quenching)

CF₄ (4k€ bottle, GWP=7390) is difficult to replace:

- drop it
- R1234ze (1.5k€ bottle, GWP=7, candidate substitute for fluorinated gas in RPC and CMS-CSC)

New mixtures with new gases

- ALICE TPC GEM Ne-N₂-CO₂ (relatively high drift velocity, negligible GWP)
