
Simplified likelihoods with linearized systematics

(“Not-so simplified likelihoods”)

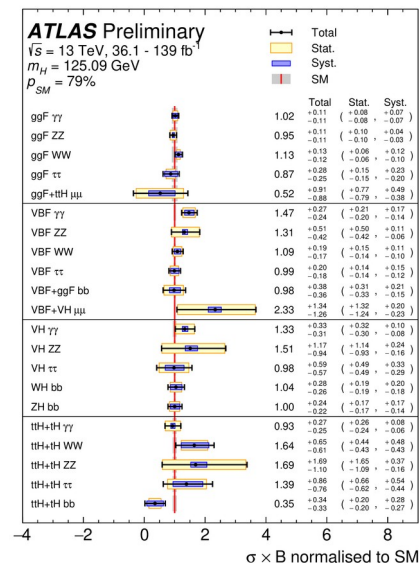

Reinterpretation of experimental results

Reusing published experimental results ?

- Combination with other results
- Reinterpretation in the context of other models

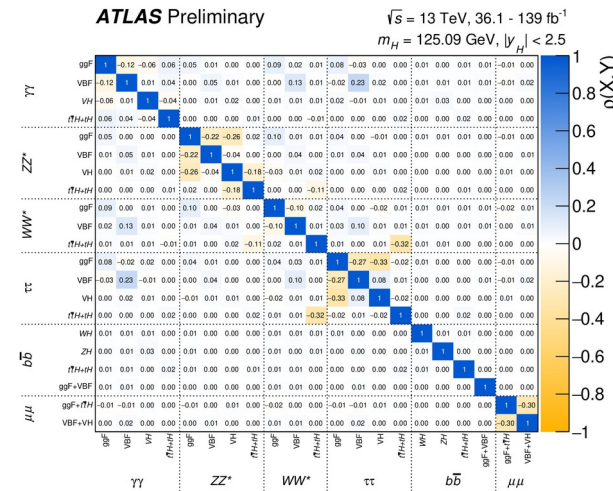

HEP experiments typically publish their results in the form of:

- central values $\pm(1,2)\sigma$ intervals, or upper limits at 95% CL
- For multiple parameters, also provide correlation matrices

Insufficient for many applications

- Covariance matrix only describes a Gaussian measurement
 \Rightarrow No reinterpretations beyond **Gaussian approximation**
- Typically only total (stat+syst) uncertainties, no breakdown
 \Rightarrow Combinations cannot account for **correlated systematics**

Likelihoods in HEP results

Usual description of LHC measurements: measurement PDF, a.k.a the **likelihood** L with

- Parameters of interest (μ)
 - Nuisance parameters (θ).
- $$\left. \begin{array}{l} \bullet \text{ Parameters of interest } (\mu) \\ \bullet \text{ Nuisance parameters } (\theta). \end{array} \right\} L(\mu, \theta)$$

The nuisance parameters describe systematics and other “nuisances” fit to data.

Profile likelihood : uses “profiled” values $\hat{\theta}(\mu)$ of the NPs = best-fit values at given POI values.

$$\Lambda(\mu) = -2 \log \frac{L(\mu, \hat{\theta}(\mu))}{L(\hat{\mu}, \hat{\theta})}$$

Used compute e.g. a confidence interval: same for upper limits, etc.

- 2000 First PHYSTAT workshop [CERN 2000-005]

Unanimous agreement that particle physicists should publish likelihood functions, given their fundamental importance in extracting quantitative results from experimental data.

- 2012 Les Houches Recommendations for the Presentation of LHC Results

Recommendation 3b: When feasible, provide a mathematical description of the final likelihood function in which experimental data and parameters are clearly distinguished, [....].

Recommendation 3c: Additionally provide a digitized implementation of the likelihood that is consistent with the mathematical description.

- 2020: Reinterpretation of LHC Results for New Physics: Status and Recommendations after Run 2 [SciPost Phys. 9, 022 (2020)]

- 2021: White paper on publishing statistical models →

Publishing statistical models: Getting the most out of particle physics experiments

Kyle Cranmer^{1*}, Sabine Kraml^{2†}, Harrison B. Prosper^{3§} (editors), Philip Bechtel⁴, Florian U. Bernlochner^{5*}, Itay M. The statistical models used to derive the results of experimental analyses are of incredible scientific value and are essential information for analysis preservation and reuse. In this paper, we make the scientific case for systematically publishing the full statistical models and discuss the technical developments that make this practical. By means of a variety of physics cases — including parton distribution functions, Higgs boson measurements, effective field theory interpretations, direct searches for new physics, heavy flavor physics, direct dark matter detection, world averages, and beyond the Standard Model global fits — we illustrate how detailed information on the statistical modelling can enhance the short- and long-term impact of experimental results.

Current Situation

- **Full likelihood** publication is gathering steam ([pyhf](#), ROOT)
 - ⊕ **Support for non-Gaussian effects**, both from small yields (Poisson PDFs) and systematics.
 - ⊕ **Independent NPs for systematics**: can properly correlate systs (not always trivial in practice!)
 - ⊖ **Models sometimes quite large**: difficult to handle and long to evaluate (few min - few hours)
 - ⊖ **More difficult to tackle unbinned models** (needs arbitrary PDFs, requires e.g. roofit...)
- **Simplified likelihoods** provide intermediate solutions. Many flavors:
 - ATLAS SUSY SLs [[ATL-PHYS-PUB-2021-038](#)] : Poisson PDFs, 1 NP for systs.
 - [Simplify](#) [[JHEP04\(2019\)064](#)] : Poisson PDFs, Keep all POIs, 1 NP per bin with quadratic impact
 - [DNNLikelihood](#) [[Eur. Phys. J. C 80, 664 \(2020\)](#)]: train a DNN to approximate the likelihood function

Simplified Likelihoods using Linearized Systematics

Requirements:

- **Describe non-Gaussian effects** from small event counts (Poisson behavior)
- **Preserve all POIs** \Rightarrow allow reinterpretation through reparameterization
- **Preserve all NPs** \Rightarrow allow correlation of systematic uncertainties

A particular use-case: SMEFT interpretations

- Reparameterize cross-section measurements using EFT Wilson coefficients: $\sigma_i = f(c_a)$
- Important constraints from both
 - High-mass tail regions (e.g. $pp \rightarrow VV, ll$) \Rightarrow need Poisson description
 - Syst. dominated precision measurements (e.g. $W, Z, \text{top}, \text{Higgs}$) \Rightarrow need accurate syst. treatment

How can we simplify ??

1. **Keep all NPs/systematics but at linear order only.**
2. **Assume all systematics are Gaussian.** (common assumption even for full likelihoods)

Starting point: the HistFactory description

Binned likelihood form, with parameters of interest (μ) and nuisance parameters (θ) :

$$L(\mu, \theta) = \prod_{c=1}^{n_{\text{channels}}} \prod_{b=b_c^{\text{first}}}^{b_c^{\text{last}}} P\left(n_b^{\text{obs}}; \sum_{s=1}^{n_{\text{samples}}} N_{s,b}^{\text{exp}}(\mu, \theta)\right) \prod_{p=1}^{n_{\text{syst NPs}}} C(a_p; \theta_p)$$

Product over channels (independent measurement regions)

Product over channel bins

Poisson PDF in each bin

Observed bin yield

Expected bin yield, function of both POIs and NPs.

- Several possible forms: linear, exponential, etc.
- Implements correlations between bins

NP constraints (from auxiliary measurements a)

Constrained nuisance parameters describe systematic uncertainties

Simplified Likelihoods with Linearized Systematics

Exact treatment
of the POI μ

NP dependence at
linear order only

→ Consider **NP effects** at **linear order only**.

$$N_{sb}^{\text{exp}}(\mu, \theta) = N_{sb}^{\text{nom}}(\mu) \left(1 + \sum_p \Delta_{sbp} \theta_p \right)$$

→ Consider only **Gaussian constraints**

↑
Impact coefficients

→ Keep **full description** of **bin counting** (Poisson PDF) and **POIs** (μ)

$$L(\mu, \theta) = \prod_{c=1}^{n_{\text{channels}}} \prod_{b=b_c^{\text{first}}}^{b_c^{\text{last}}} P \left(n_b^{\text{obs}} ; \sum_{s=1}^{n_{\text{samples}}} N_{sb}^{\text{exp}}(\mu, \theta) \right) \prod_{p=1}^{n_{\text{non-free NPs}}} C(a_p ; \theta_p)$$

$$L(\mu, \theta) = \prod_{c=1}^{n_{\text{channels}}} \prod_{b=b_c^{\text{first}}}^{b_c^{\text{last}}} P \left(n_b^{\text{obs}} ; \sum_{s=1}^{n_{\text{samples}}} N_{sb}^{\text{nom}}(\mu) \left(1 + \sum_p \Delta_{sbp} \theta_p \right) \right) G(\theta_p^{\text{obs}} ; \theta_p, \Gamma^{-1})$$

Linear NP impacts

Gaussian constraints

Simplified Likelihoods with Linearized Systematics

- Consider **NP effects** at **linear order only**.
- Consider only **Gaussian constraints**
- Keep **full description** of **bin counting** (Poisson PDF) and **POIs** (μ)

Benefit: fast profiling!

- Minimization wrt NPs is a simple matrix operation

P, Q matrices built from N^{nom}, b and D

$$\hat{\theta}(\mu) = [\Gamma + P(\mu)]^{-1} [\Gamma \theta^{\text{obs}} - Q(\mu)]$$

- **Obtain the profile likelihood $\Lambda(\mu)$ more quickly than with the full likelihood.** POIs are treated exactly (non-linear minimization, as in full likelihood). Typically $N_{\text{POIs}} \ll N_{\text{NPs}} \dots$
- All NPs retained: can correlate everything across measurements as for full likelihoods
- Usually an excellent approximation
 - Searches have small systematics \Rightarrow OK to linearize
 - Precision measurements often in Gaussian regime \Rightarrow well described by linear systematics.
- Cannot describe asymmetric and non-Gaussian uncertainties

Simple example

Simple S+B counting experiment, $B = 2 \pm 0.2$, observe $n=3$

Describe the uncertain background using an NP:

$$L(s, b) = \text{Pois}(3, s + b) G(2; b, 0.2)$$

In this (simple!) case, can compute everything in closed form

SLLS gives very precise estimation of $\Lambda(s)$ and $\hat{b}(s)$

⇒ Describes both Poisson effects and systematics.

$$\hat{b}(s) = \frac{1}{2} \left[\sqrt{(s + b_0 - b_0^2 \epsilon^2)^2 + 4b_0^2 \epsilon^2 n} - (s - b_0 + b_0^2 \epsilon^2) \right]$$

$$\Lambda(s) = 2(s - \hat{s} + \hat{b}(s) - \hat{b}) - 2n \log \left(\frac{s + \hat{b}(s)}{\hat{s} + \hat{b}} \right),$$

Not-so-simple Example: ATLAS SUSY search in trilepton states

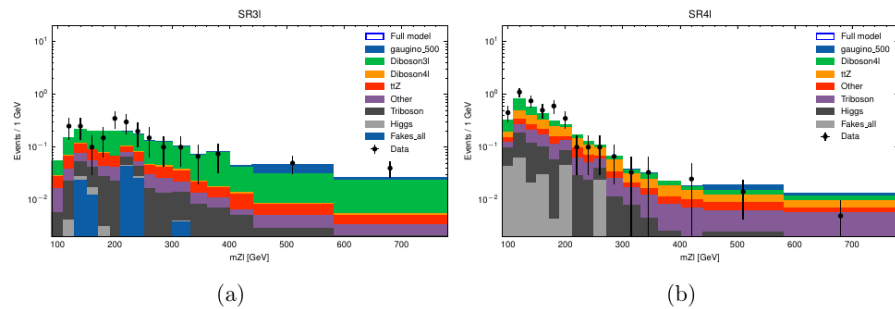

ATLAS search for charginos in trilepton final states ($\chi^+ \rightarrow Z(\ell)\ell$) from [Phys. Rev. D 103, \(2021\) 112003](#)

- 3 signal regions (3l, 4l, full-reco (FR)), binned in $m_{Z\ell}$.
- 3 control regions for main backgrounds (CRWZ, CRZZ, CRttZ)

ATLAS SUSY search in trilepton states

- Use the [pyhf workspace](#) description of the analysis likelihood, available on HEPdata
- Produce a SLLS linearized likelihood using an automatic script.
- Check profile likelihood scan and profiled values for various model points
- <1s per fit on a laptop, O(1000) faster than full L

Models described in previous slides are **binned** : just counting events in bins.
 Some analyses with smooth backgrounds ($H/X \rightarrow \gamma\gamma$, $H \rightarrow \mu\mu$, $X \rightarrow jj$, ...) typically use **unbinned** modeling instead \rightarrow Describe the shape of a continuous observable

Difficult problem: need to implement **all** the PDFs required to model signal and background.

\rightarrow Can describe the unbinned distribution as a set of very fine bins, and go back to a binned description

\rightarrow Large number of bins required, but feasible for simplified models.

Unbinned example: toy $H \rightarrow \gamma\gamma$ measurement

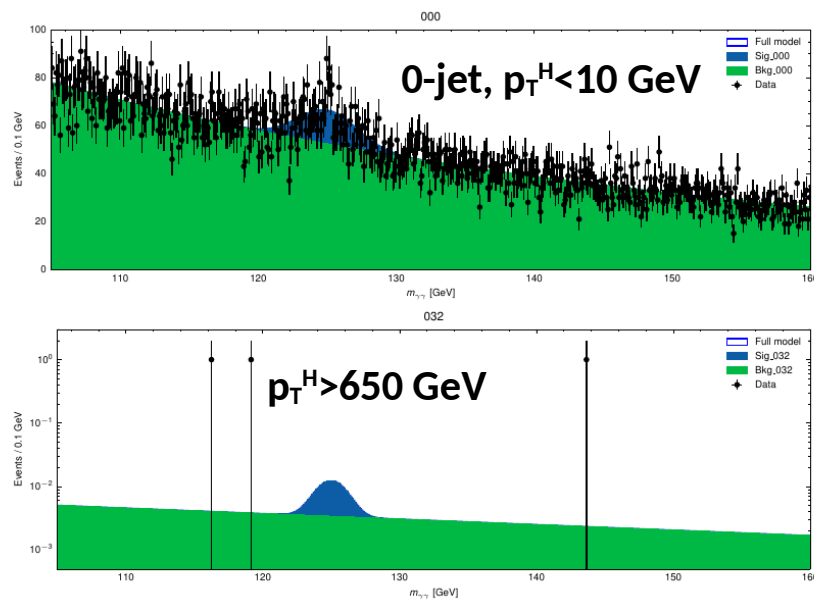

Build a toy unbinned likelihood from the ggF and VBF regions of the ATLAS $H \rightarrow \gamma\gamma$ measurement in 2207.00348.

Full model: unbinned measurement of μ over $105 < m_{\gamma\gamma} < 160$ GeV, in 33 measurement regions.

SLLS: discretize into bins of 0.1 GeV ($\ll \sigma_H \sim 1-2$ GeV)

\Rightarrow 18150 bins in total (!) but still rather fast:

- ~ 50 ms per fit with fixed μ
- ~ 1 s per fit for floating μ .

Unbinned example: toy H→γγ measurement

Profile likelihood scan

Profiled values of syst NPs

Conclusion

- **Simplified likelihoods** are a critical ingredient for accurate real-world reinterpretation/reuse
- **SLLS likelihoods** provide a simplified description that retains key aspects:
 - Poisson description of event counts
 - all parameters of interest
 - all nuisance parameters
 - More details in [arXiv:2301.05676](https://arxiv.org/abs/2301.05676)
- **Linearized NP impacts** allow profiling through matrix algebra, which is very fast .
 - ~1s per full fit, $O(10 \text{ ms})$ for profiling NPs.
 - Typically model setup times are longer (few seconds to load all the coefficients)
- **Other simplified approaches available:**
 - ATLAS SUSY SLs [[ATL-PHYS-PUB-2021-038](https://arxiv.org/abs/2103.03038)] : Poisson PDFs, 1 NP for systs.
 - [Simplify](https://arxiv.org/abs/1905.05521) [[JHEP04\(2019\)064](https://arxiv.org/abs/1905.05521)] : Poisson PDFs, Keep all POIs, 1 NP per bin with quadratic impact
 - DNNLikelihood [[Eur. Phys. J. C 80, 664 \(2020\)](https://arxiv.org/abs/1905.05521)]: train a DNN to approximate the likelihood.
- Hopefully all useful for further likelihood publications and reuse!
