

Rucio Token Workflow Evolution

Martin Barisits, Dimitrios Christidis

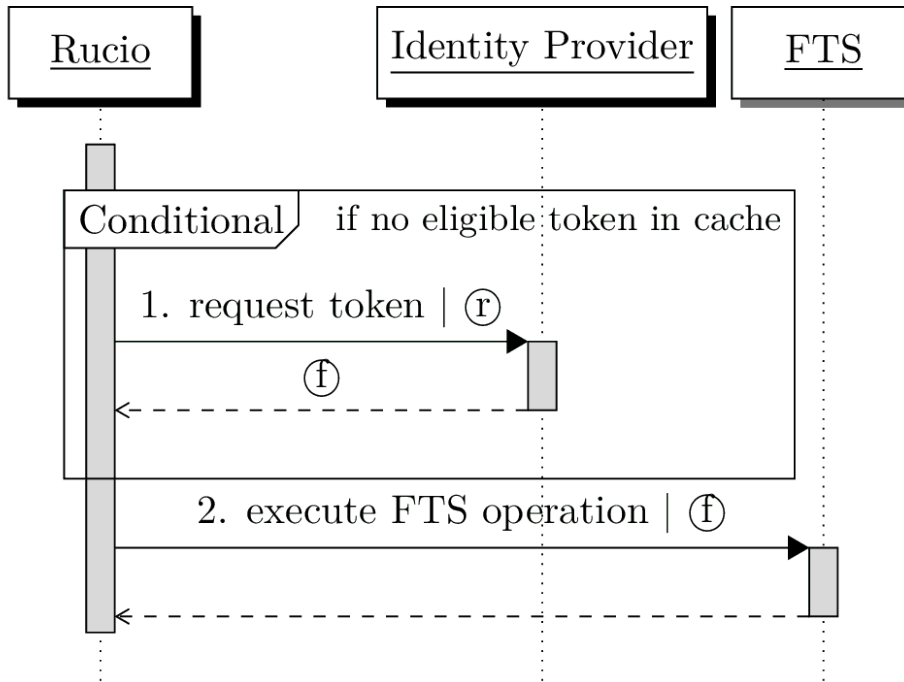

Introduction

- The [Rucio Tokens SIG](#) has been launched
- Version [0.1 of the design document](#) is now available
 - Expresses our current understanding and plans
 - Will continue to evolve with the development and together with input from the community
 - Some topics will be added as soon as they become clear
 - Some existing details might change
- New development may supersede existing functionality

The Workflows

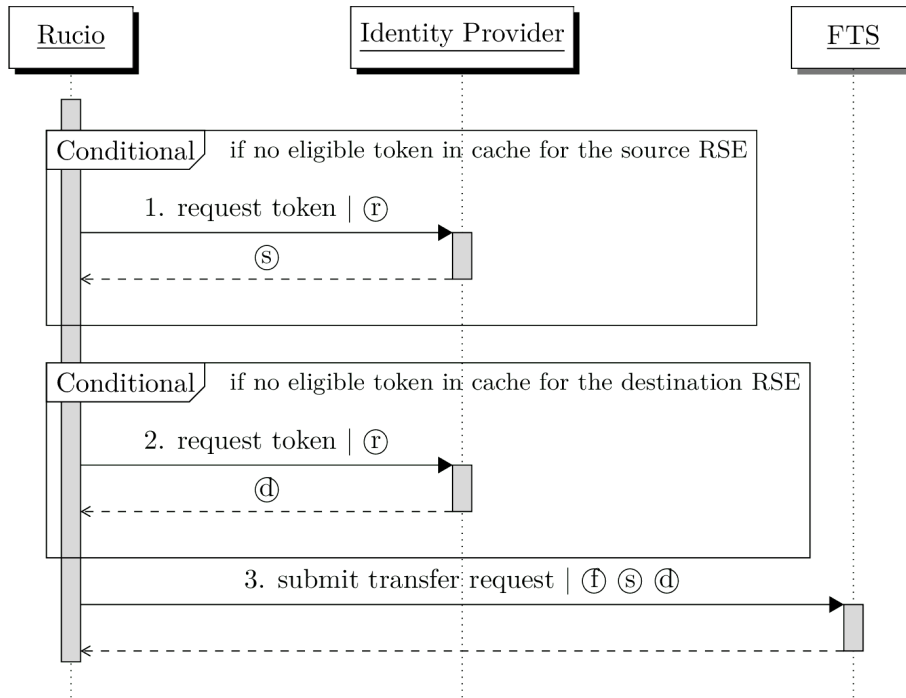

- Central
 - Third-Party-Copy Transfer
 - Deletion
- User
 - Authentication
 - Download
 - Upload

Third-Party-Copy Transfer (1)

- First, obtain a token providing authentication with an FTS instance
- Erratum: authentication method must match what is used for the transfer

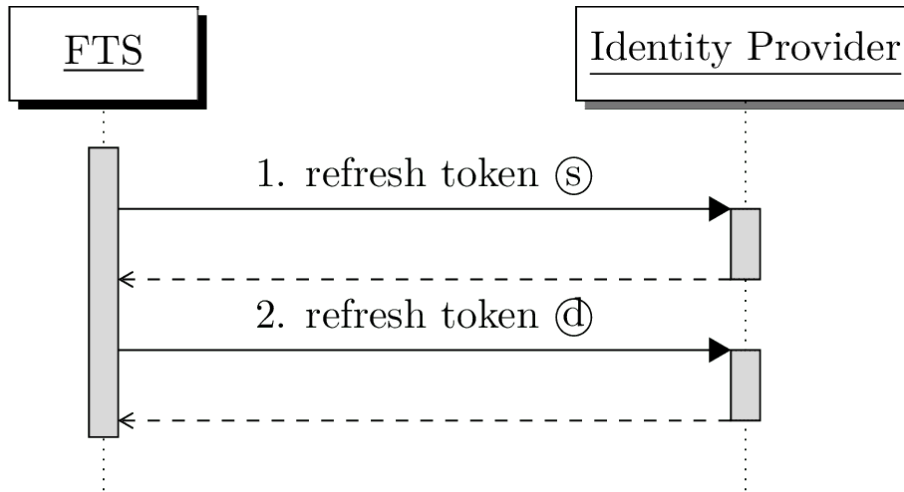

Third-Party-Copy Transfer (2)

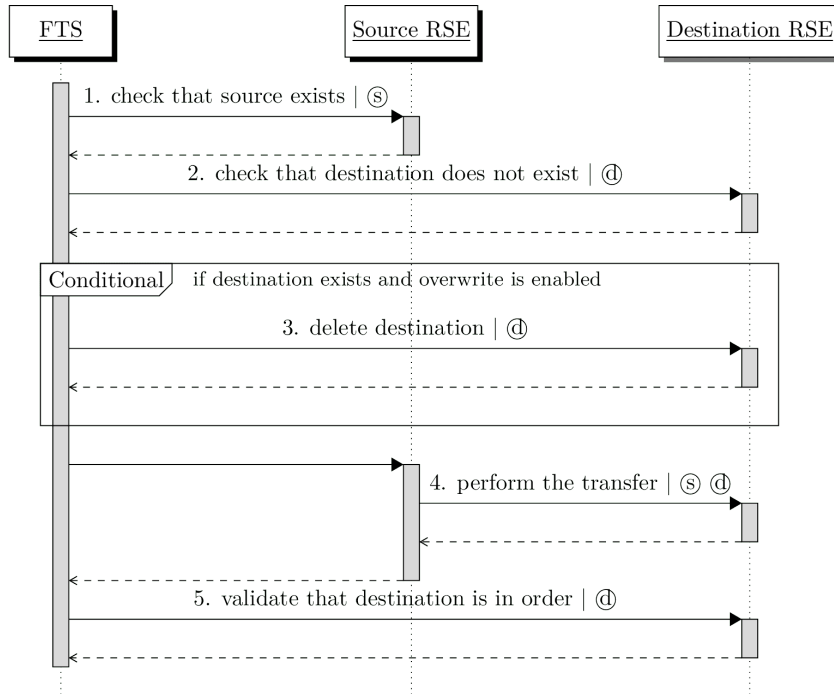

- Second, obtain tokens for reading from the source RSE and writing to the destination RSE, then submit the transfer request
- Similar for more complex transfers (e.g. multi-source, multi-hop, tape storages)

Third-Party-Copy Transfer (3)

- Third, FTS is responsible for refreshing the provided tokens until the transfer is activated

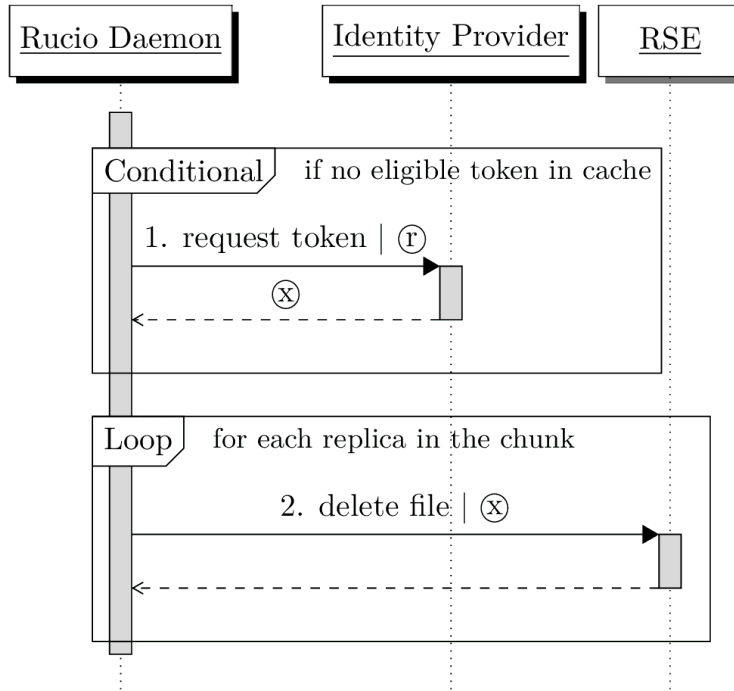

Third-Party-Copy Transfer (4)

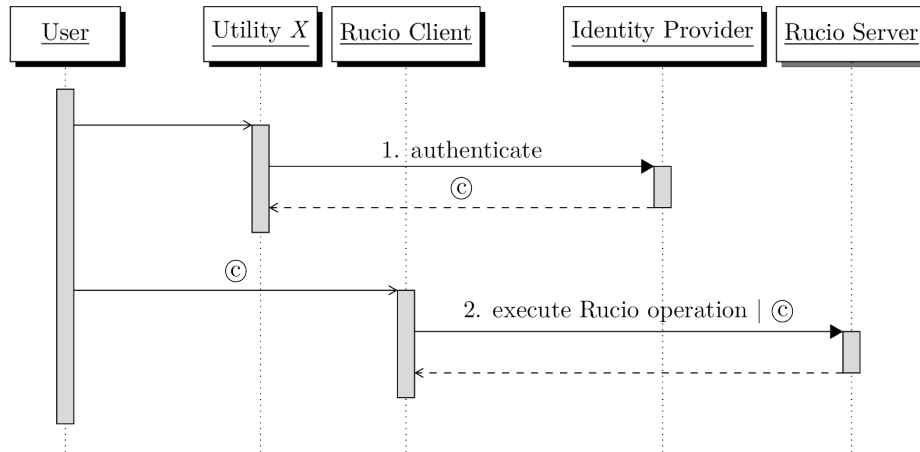

- Finally, FTS performs the actual transfer
- This is an initial design
 - FTS expects the destination token \textcircled{d} to be capable of deletion
 - A second design in the works

Deletion

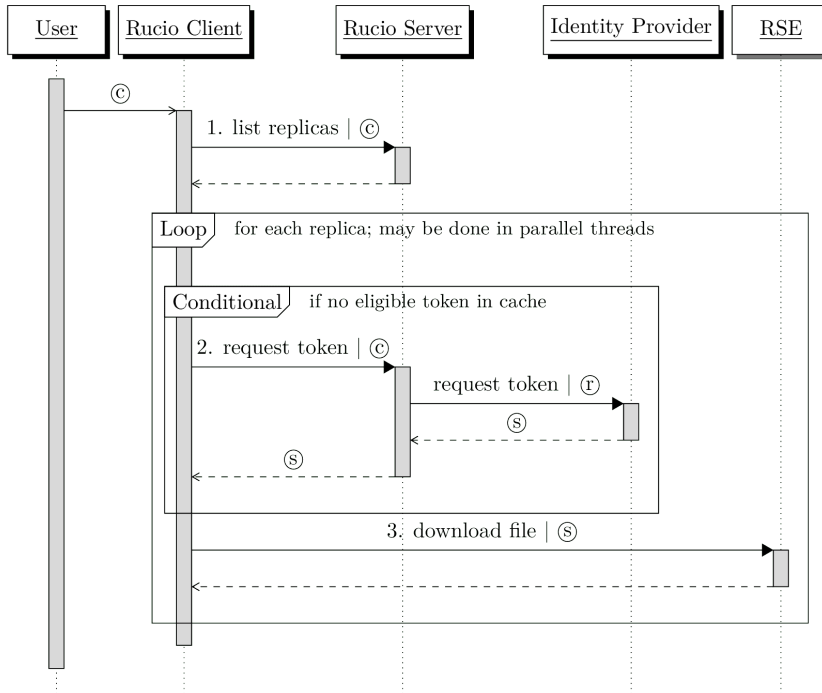

- Very little change compared to X.509

Authentication

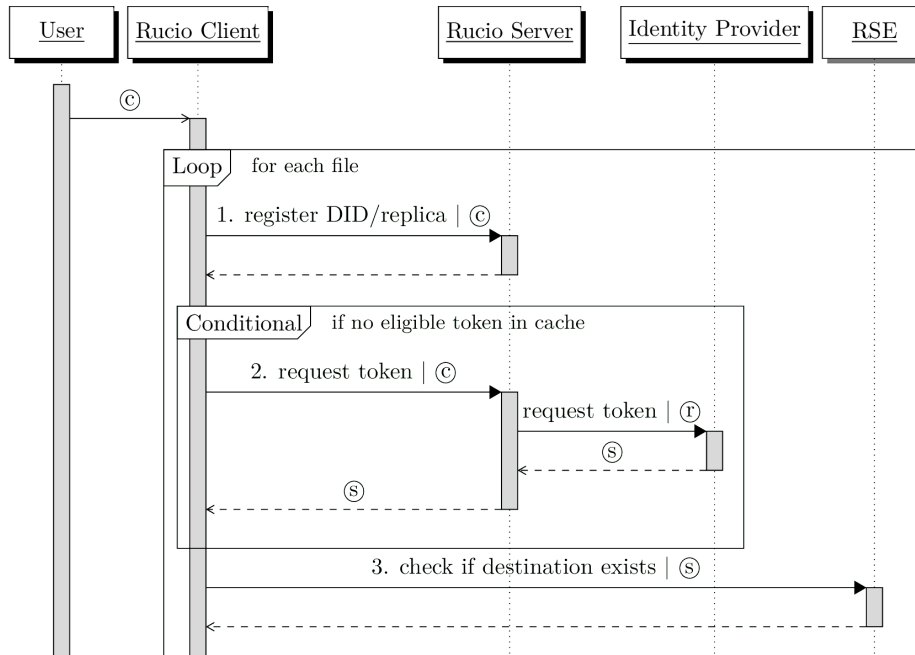

- We expect some form of external utility like `voms-proxy-init`
 - For now, the placeholder name 'utility X' is used
- Not an actual requirement for upload/download using tokens

Download

- Requires a new endpoint in the REST API
- Might require some form of token introspection in the client

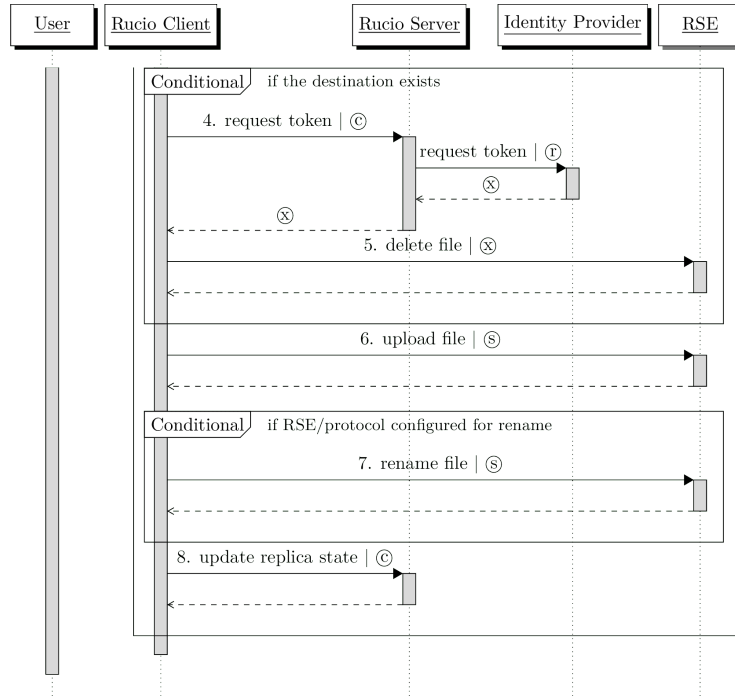

Upload (1)

- Similar to the download workflow

Upload (2)

(Continued from previous slide)

- Added complexity due to the client potentially needing to delete

Plugin-Based Approach

- No single solution that satisfies all
- Envisioned areas:
 - Identity provider (INDIGO IAM, CILogon)
 - Token profile (WLCG)
 - Audience restrictions (RSE hostnames, WLCG 'any')
 - Scope restrictions
 - Namespace access

`/eos/atlas/atlasdatadisk/rucio/mc16_13TeV/00/ff/AOD.23208852._003398.pool.root.1`

Diagram illustrating the structure of a file path with annotations:

- prefix** (green box): `/eos/atlas/atlasdatadisk/rucio/`
- scope** (orange box): `/eos/atlas/atlasdatadisk/rucio/mc16_13TeV/00/ff/`
- file** (red box): `AOD.23208852._003398.pool.root.1`

Hybrid Functionality

- For communities depending on X.509, the transition must be allowed to happen progressively
- An RSE attribute for most workflows
 - For TPC, must be all RSEs related to a transfer job
 - Won't support a situation where an RSE supports only tokens while others use X.509
- Account identities for user authentication

Questions?
