8TH INTERNATIONAL CONNECTING THE DOTS WORKSHOP

Quirk Introduction

Quirks are stable BSM particles that are charged under an unbroken non-Abelian gauge force which confines at low energies:

- Used in models of dark matter, little Higgs scenarios, folded SUSY...

Quirks are characterized by a hidden QCD-like confinement scale Λ and mass m_Q with:

$$\Lambda \ll m_Q$$

- Once produced quirks are separated by a QCD-like color-string which keep the quirk pair neutral
- But as opposed to the SM, the small energy stored in the string is insufficient to produce a quirk pair and thus preventing hadronization

Quirks are subjected to a restoring force with the scale Λ^2 and exhibit oscillations on the scale

$$d \sim 2 \text{ cm} \left(\frac{m_Q}{100\text{GeV}} \right) \left(\frac{\text{keV}}{\Lambda} \right)^2$$

[0805.4642](https://arxiv.org/abs/0805.4642)

Quirk Introduction

Some previous works include:

- [Stopping Quirks at the LHC](#)
 - Look for quirks that stop in the detector and produce hits that are out of time with any bunch crossing
- [Tracking down Quirks at the LHC](#)
 - Recognize that quirks are subject to a central force, and so their hits lie along the plane
- [The Quirk Signal at FASER and FASER2](#)
 - String tension forces quirks to be dominantly produced with a zero net pT → look in the forward direction

[1708.02243](#)

While these explorations probe large regions of parameter space, they struggle when oscillations are on the scale of meters.

[2108.06748](#)

What's the plan

We can't use the standard tracking tools to find these quirk tracks because they are not helices, and writing a dedicated quirk tracker would require a complete rewrite.

➤ Use the more flexible ML-based tracking algorithm to learn maybe a good way to find quirks.

1. Does the GNN tracking work for non-helical tracks?
 2. When it is trained on SM (i.e. mostly helical) tracks, can it work on non-helical?
 3. When it is trained on non-helical, can it work on non-helical?
- Train on SM, validate on quirk
 - Train on well-behaved quirks, validate on well-behaved quirks
 - Train on all quirks, validate on all quirks

Dataset

- Use MG5 generate samples through $pp \rightarrow Q\bar{Q} + j$:
 - Quirk: Collect Quirk and through a simplistic model of the ATLAS detector which consists of **8 layers** of trackers.
 - A 500 GeV quirk pair with the string tension (Lambda) = 500 eV (The small Lambda don't have non-helical tracker)
 - Background: Jet (~100 particles for one event)

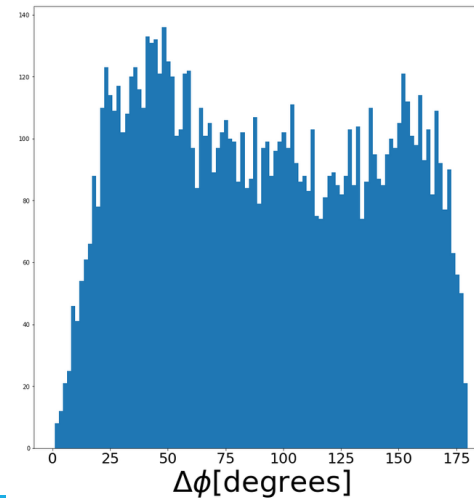

[1708.02243](#)

- Check on the quirk dataset:
 - Uniform opening angle
 - ~500 GeV momenta
 - Some asymmetry, the typical case is $\vec{p}_1 = \vec{p}_2$.

Quirk non-helical tracks:

Bkg tracks:

Quirk Dataset

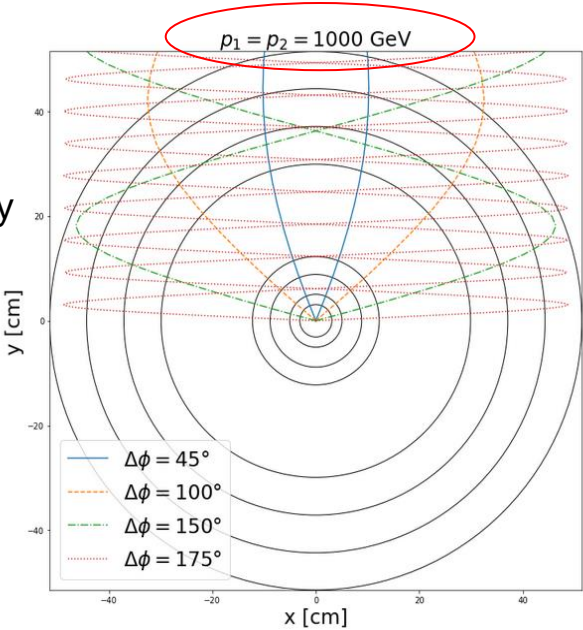

Quirks come out at a variety of momenta with different opening angles.

◆ Let's set $\vec{p}_1 = \vec{p}_2$, and look at trajectories for different opening angles centered on y axis

Too soft to separate → 8 hits per quirk:

For $\phi < 100$, can still have only 8 hits, otherwise very many:

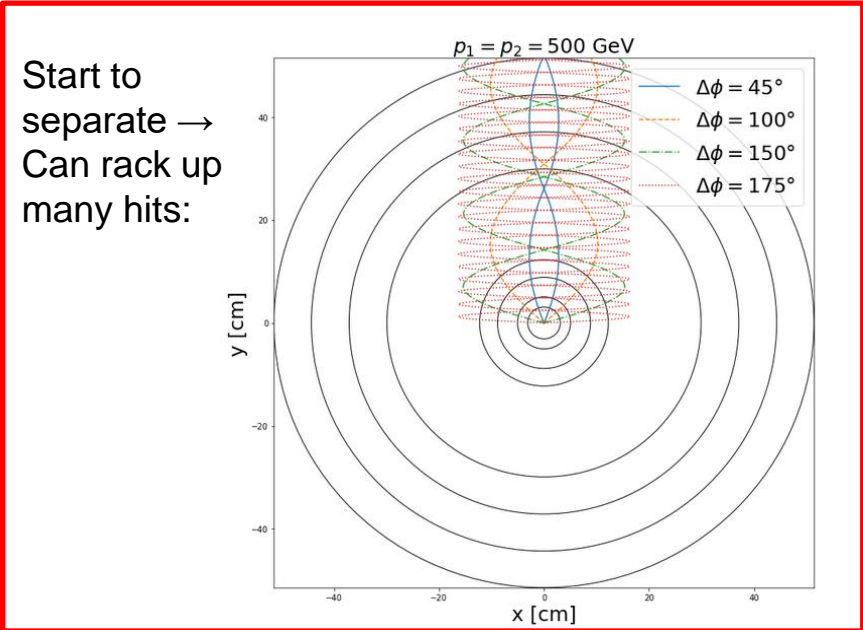

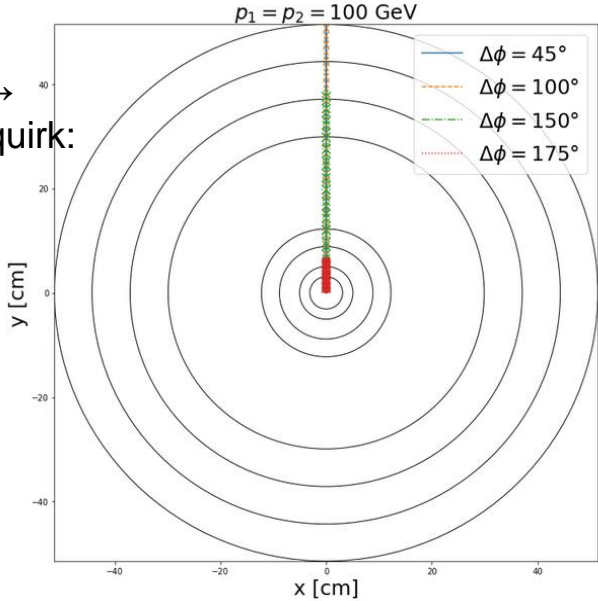

Quirk Dataset

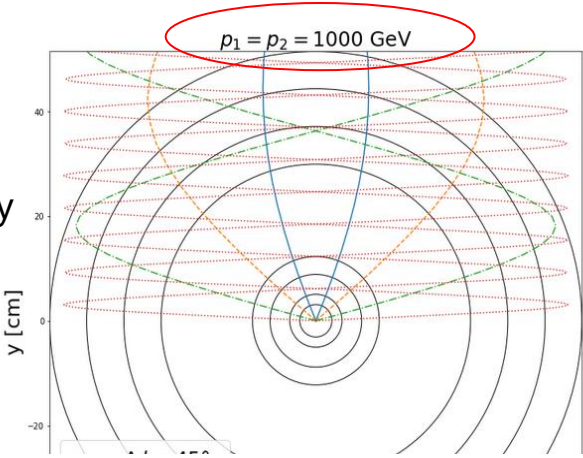

Quirks come out at a variety of momenta with different opening angles.

◆ Let's set $\vec{p}_1 = \vec{p}_2$, and look at trajectories for different opening angles centered on y axis

Too soft to separate → 8 hits per quirk:

For phi < 100, can still have only 8 hits, otherwise very many:

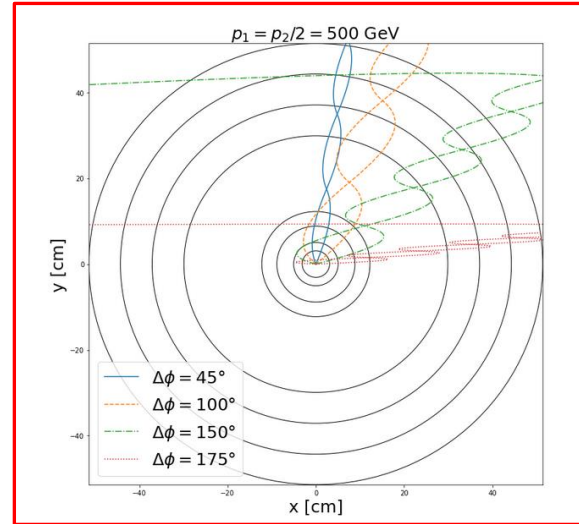

- We rack up many hits for only large opening angles, but typically get ~30+
- Looking at the actual data, median of 26 hits (13 for each quirk)

Dataset for training

Now let's study some asymmetry and set $p_1 = p_2 / 2$ for example.

A coupled pendulum... Crazy tracks... Hard to reconstruct and training.

We focus on one simple category of quirk tracks initially (This is the first study for well-behaved quirks), so we do the simple selection on Quirk dataset:

- Opening angle $< 50^\circ$
- $N_{hit} < 20$

Separate the Background and Quirk dataset for analysis:

- Background training, quirk inference (1000 events to train on)
- Quirk training, quirk inference (800 events to train on)

Pipeline

Based on [Exa.Trkx](#).

Defining “True neighbors”:

- For each particle, order hits by increasing the “hit_id”
- Group by shared module ID
- Connect all combinations from layer L_i to L_{i+1}

Metric Learning:

- For all hits in detector, embed features into N-dimensional space.
- Associate neighboring hits as close in N-dimensional distance.
- Score each “neighbour” hit within embedding neighborhood against the “target” hit at centre.

Results: Background training, quirk inference

Background training, background inference: 97.9% reconstructed efficiency

The track definition

$$|\eta| < 4$$

$$n_{track}^{hits} \geq 5$$

$$n_{particle}^{hits} \geq 7$$

Double-majority
matching

Background training, quirk inference: 10.2% reconstructed efficiency

Distribution of reconstructed quirks

The distribution of reconstructed quirks' information:

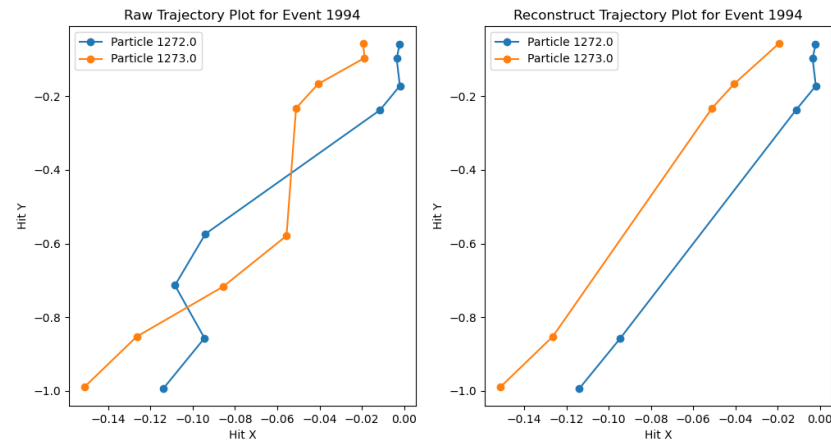

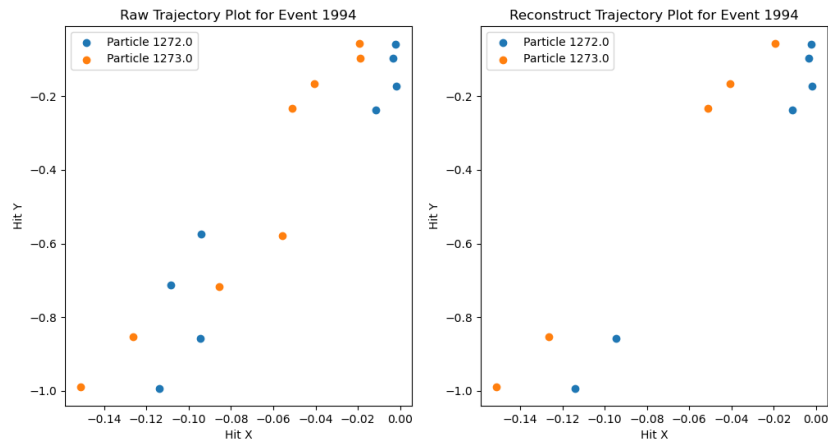

- $r, \phi, z(cm)$ are truth information of hits. r is scaled to $(0,1)$. The plots are shown in the [backup](#).
- n_{reco}^{hits} is the number of reconstructed hits, n_{truth}^{hits} is the number of truth hits.

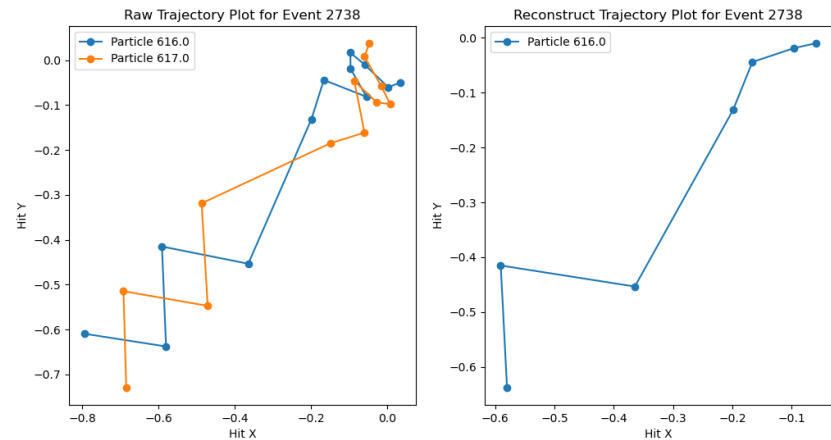

Reconstructed hits of quirk

With same event (use the reconstructed event information):

- Some $\text{hits}_{\text{reco}}$ are the part of truth quirk track.

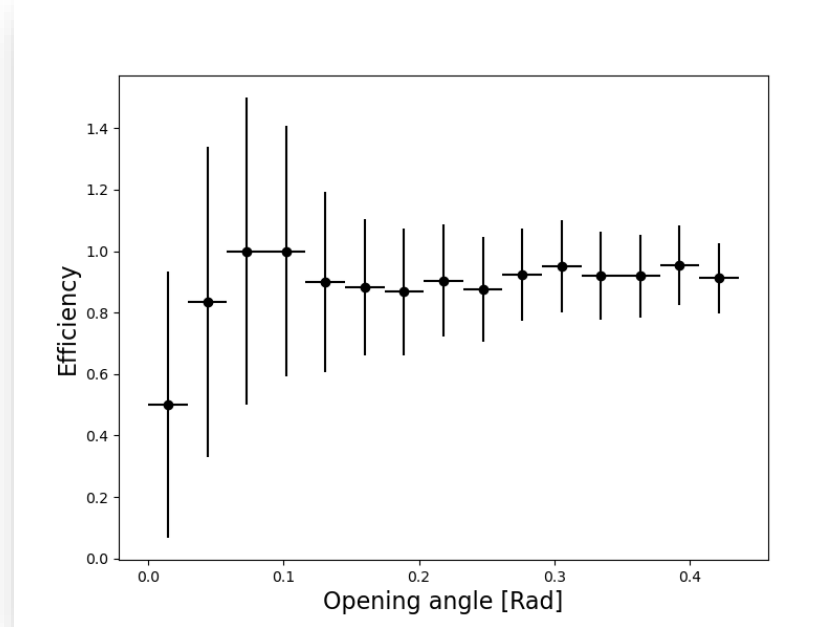

- Only reconstruct **simple and smooth** track. (The particle 617 is failed to be reconstructed)

Results: Quirk training, quirk inference

Well-behaved Quirk training, quirk inference: **92.8%** reconstructed efficiency

➤ The opening angle has no impact on the Quirk reconstruction efficiency in well-behaved Quirk training.

Distribution of reconstructed quirks

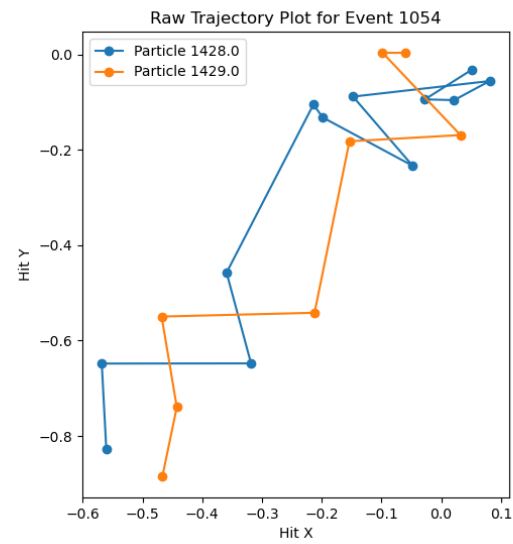

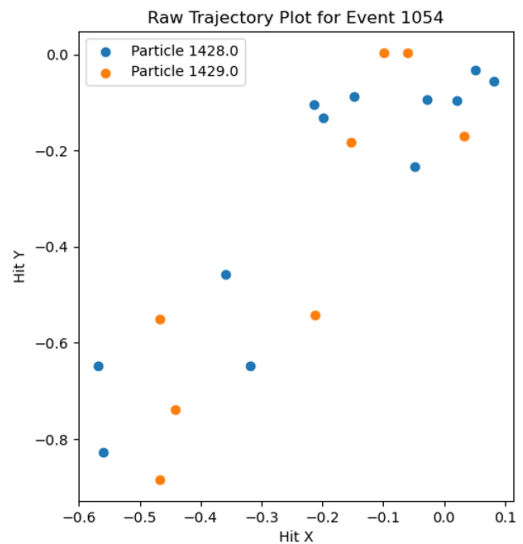

The distribution of reconstructed quirks' information:

- $r, \phi, z(cm)$ are truth information of hits. r is scaled to $(0,1)$. The plots are shown in the [backup](#).
- n_{reco}^{hits} is the number of reconstructed hits, n_{truth}^{hits} is the number of truth hits.

Reconstructed hits of quirk

All of well-behaved quirks are reconstructed well even though the dot plot looks chaos:

Results: All Quirk training, quirk inference

When we training on all quirks without pre-selection, the performance has dropped significantly:

56.3% reconstructed efficiency

➤ Reconstruction efficiency decreases as the opening angle increases.

Reconstructed hits of quirk

When tracks become crazy with lots of hits and in-out layers, the reconstructed performance is bad:

Well-behaved quirks (small n_{hits} or opening angle) are still reconstructed well:

Conclusion and future work

- We show that ML-based tracking can learn to reconstruct non-helical tracks with high efficiency when training on non-helical tracks. That will allow for powerful new quirk searches and open the door to other weird-track searches
- Could use non-helical tracks as a tool to understand GNN reconstruction on helical tracks, or hard-to-reconstruct SM particles

Next step:

- Generate more events and add more layers.
- Modify the pipeline to improve the results.
- Considering noise.

Backup

Metric Learning: Background training, quirk inference

Use metric learning to reduce the dimension: Embedding the space points on to graphs.

After Embedding:

GNN: Background training, quirk inference

Train GNN to classify edges as either “true” (belonging to the same track) or “false” (not belonging to the same track)

Performance – Tracking definitions

Physics cuts: $\{|\eta| < 4\}$

Some selection for reconstructed particles: For bkg, we have 8 true hits for each particles, for quirk, we have ≥ 8 true hits.

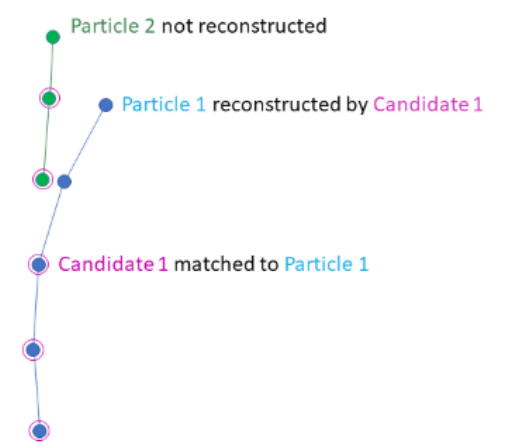

- min_reco_length: 5 (Reconstructable)
- min_truth_length: 7

- Matching style: Two_way

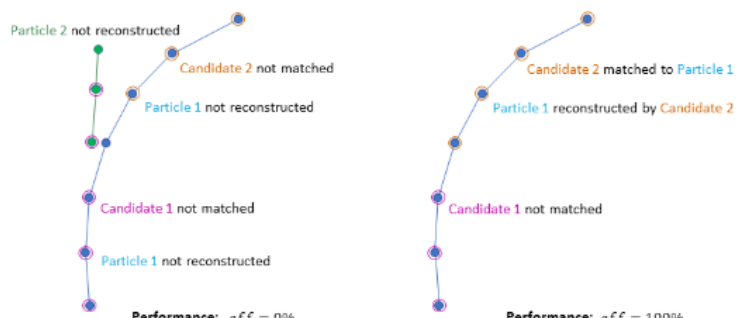

Two-Way Matching

Description: A particle is **reconstructed**, and a track is **matched**, if over MF% of each of their hits are shared by each other. Therefore, a track is uniquely **matched** to the particle it **reconstructs**.

Performance: $eff = 50\%$
 $FR = 0\%$
 $DR = 0\%$

Other examples:

Performance: $eff = 0\%$
 $FR = 100\%$
 $DR = 0\%$

Performance: $eff = 100\%$
 $FR = 50\%$
 $DR = 0\%$

Distribution of reconstructed quirks

The distribution of reconstructed quirks' information:

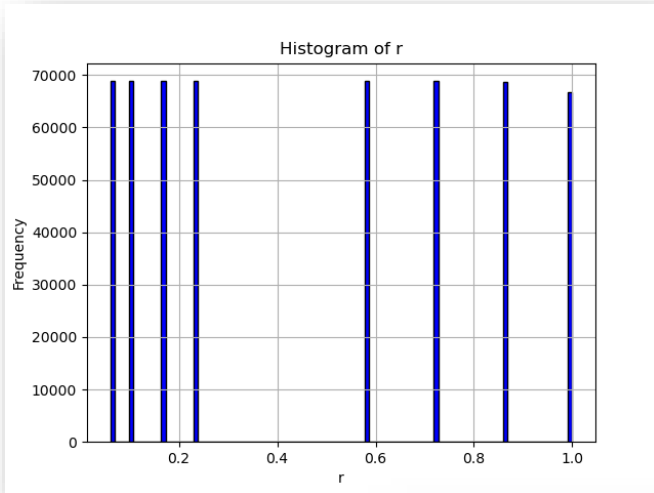

- $r, \phi, z(cm)$ are truth information of hits. r is scaled to $(0,1)$.
- n_reco_hits is the number of reconstructed hits, n_true_hits is the number of truth hits.

Distribution of reconstructed background

The distribution of reconstructed bkg(SM)s' information:

- The reconstructed information is similar as the truth information (n_hits)

Reconstructed hits of quirk

With same event (use the reconstructed event information):

- Some hits_{reco} are the part of truth quirk track.
- Only reconstruct **simple and smooth** track.
