# High-energy cosmic neutrinos

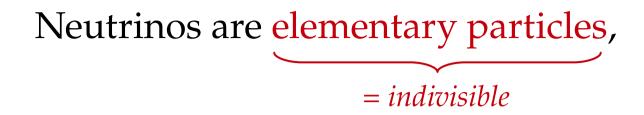

# Neutrinos are elementary particles,

electrically neutral,

very light,

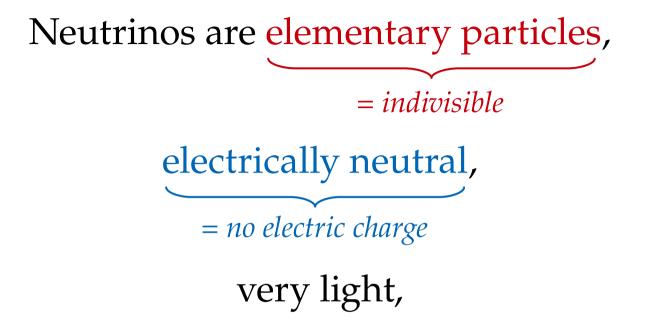

and superbly antisocial

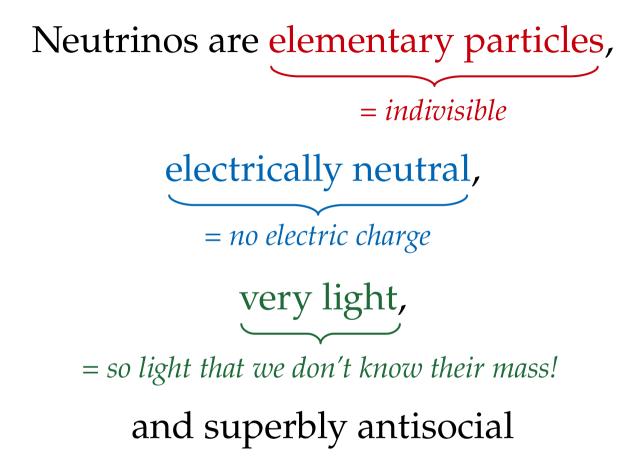

electrically neutral,

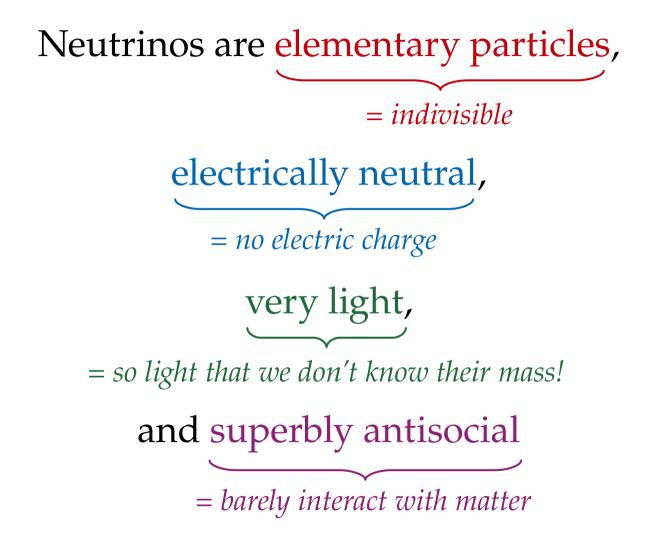

very light,

and superbly antisocial

and superbly antisocial

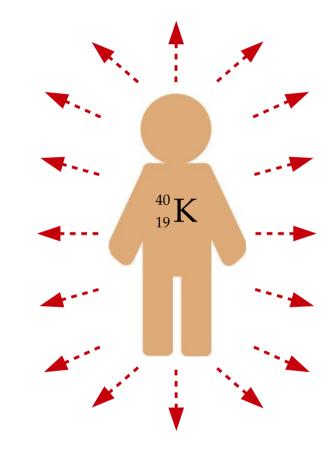

Neutrinos are everywhere: even *you* make them!

Some of the potassium in bananas is radioactive

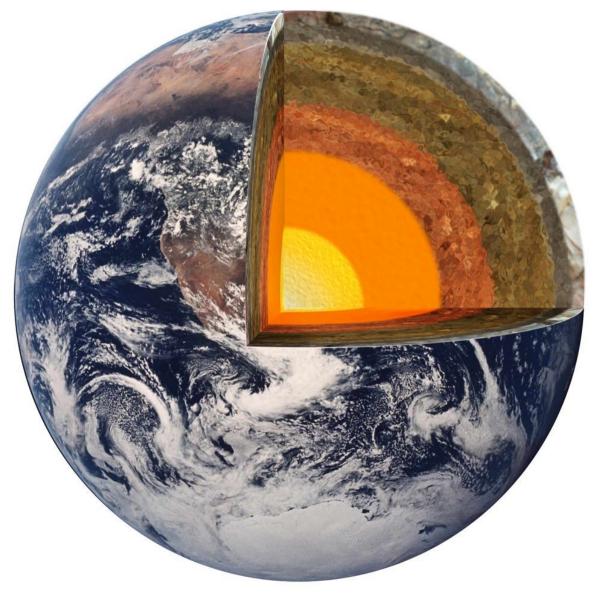

Potassium-40 has a half-life of ~ 1 billion years:

$$e^{-} + {}^{40}_{19}\mathrm{K} \longrightarrow {}^{40}_{18}\mathrm{Ar} + \mathbf{v}_{e}$$
  
$${}^{40}_{19}\mathrm{K} \longrightarrow {}^{40}_{18}\mathrm{Ar} + e^{+} + \mathbf{v}_{e} + \gamma$$
  
$${}^{40}_{19}\mathrm{K} \longrightarrow {}^{40}_{20}\mathrm{Ca} + e^{-} + \overline{\mathbf{v}}_{e}$$

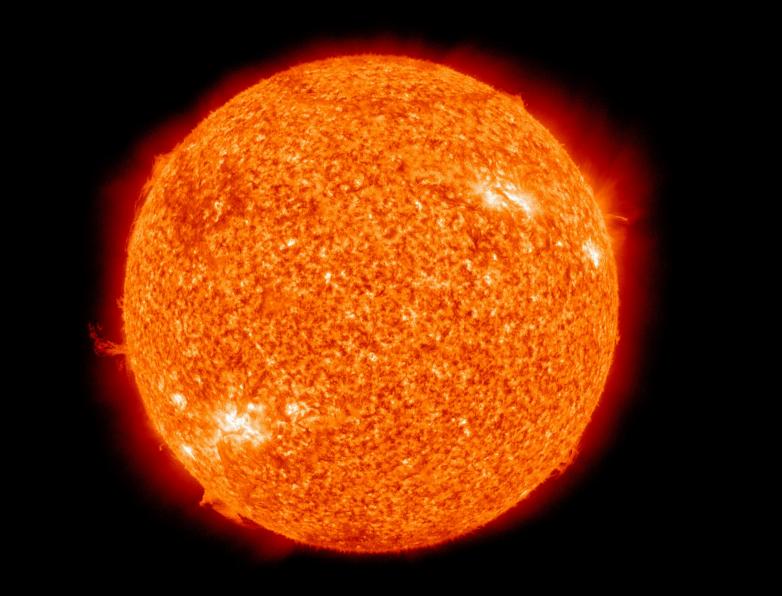

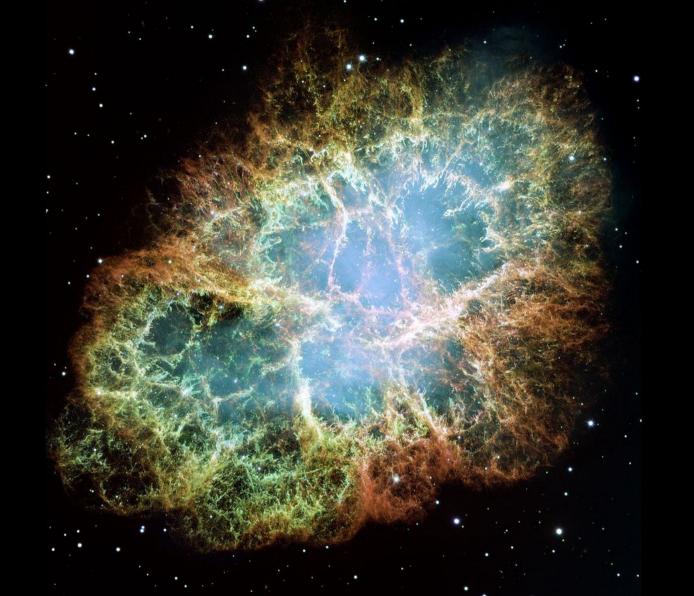

4000+ neutrinos emitted each second by a 70-kg person

# Making high-energy astrophysical neutrinos: a toy model (or p + p)

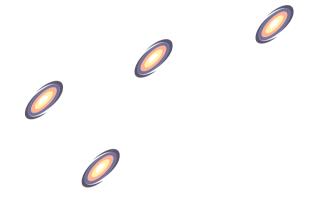

$$p + \gamma_{\text{target}} \rightarrow \Delta^{+} \rightarrow \begin{cases} p + \pi^{0}, \text{ Br} = 2/3 \\ n + \pi^{+}, \text{ Br} = 1/3 \end{cases}$$
$$\pi^{0} \rightarrow \gamma + \gamma$$
$$\pi^{+} \rightarrow \mu^{+} + \nu_{\mu} \rightarrow \bar{\nu}_{\mu} + e^{+} + \nu_{e} + \nu_{\mu}$$
$$n \text{ (escapes)} \rightarrow p + e^{-} + \bar{\nu}_{e}$$

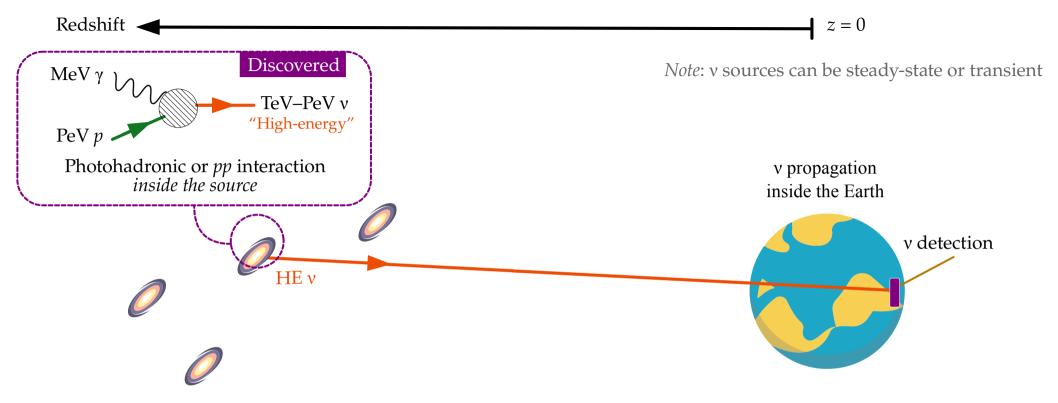

Neutrino energy = Proton energy / 20 Gamma-ray energy = Proton energy / 10

	Redshift 🚽	z = 0	0
--	------------	-------	---

*Note*: v sources can be steady-state or transient

### How many neutrinos? The Waxman-Bahcall bound

- ► Energy production rate of extragalactic cosmic-ray protons in the energy range 10<sup>19</sup>–10<sup>20</sup> eV:  $\dot{\varepsilon}_{CR}^{[10^{19},10^{21}]} \sim 5 \cdot 10^{44} \text{ erg Mpc}^{-3} \text{ yr}^{-1}$
- So, the energy-dependent generation rate of cosmic rays is  $E_{CR}^2 \frac{d\dot{N}_{CR}}{dE_{CR}} = \frac{\dot{\varepsilon}_{CR}^{[10^{19},10^{21}]}}{\ln(10^{21}/10^{19})} \approx 10^{44} \, \mathrm{erg} \, \mathrm{Mpc}^{-3} \, \mathrm{yr}^{-1}$
- ▶ Protons lose a fraction  $\epsilon < 1$  in photohadronic production of pions in the sources
- ► Present-day energy density of  $v_{\mu} + \bar{v}_{\mu}$ :  $E_{\nu}^{2} \frac{dN_{\nu}}{dE_{\nu}} \approx \frac{1}{4} \epsilon t_{\rm H} E_{\rm CR}^{2} \frac{dN_{\rm CR}}{dE_{\rm CR}}$ Br( $p + \gamma \rightarrow \pi^{+}$ ) = 0.5 × Fraction of  $\pi$  energy going to  $v_{\mu} + \bar{v}_{\mu}$  Hubble time:  $t_{\rm H} \sim 10^{10}$  yr
- ► Maximum neutrino intensity is for  $\epsilon = 1$ :  $I_{\text{max}} \approx \frac{1}{4} \xi_z t_{\text{H}} \frac{c}{4\pi} E_{\text{CR}}^2 \frac{d\dot{N}_{\text{CR}}}{dE_{\text{CR}}} \approx 1.5 \cdot 10^{-8} \xi_z \text{ GeV cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$
- So the expected neutrino flux is  $E_{\nu}^2 \Phi_{\nu\mu} \equiv \frac{c}{4\pi} E_{\nu}^2 \frac{dN_{\nu}}{dE_{\nu}} = \frac{1}{2} \epsilon I_{\text{max}}$

Waxman-Bahcall bound:  $E_{\nu}^2 \Phi_{\nu\mu} \approx 0.75 \cdot 10^{-8} \xi_z \epsilon \,\mathrm{GeV \, cm^{-2} \, s^{-1} \, sr^{-1}}$ 

Waxman & Bahcall, PRD 1999

The need for km-scale detectors

Predicted by Waxman-Bahcall 1998
Neutrino flux at TeV–PeV:  $E^2 \cdot \Phi \sim 10^{-8} \text{ GeV cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ 

Neutrino-nucleon cross section:  $\sigma_{vp} \sim 10^{-35} \text{ cm}^2 (E/\text{GeV})^{0.36}$   $\sigma_{pp} \sim 10^{-28} \text{ cm}^2$   $\sigma_{vp} \sim 10^{-29} \text{ cm}^2$ 

Number of detected neutrinos from half the sky in 1 yr:

$$N = (n_{\text{nucl}} \cdot V_{\text{det}}) \cdot (2\pi) \cdot (1 \text{ yr}) \cdot \int_{100 \text{ TeV}} \Phi(E) \cdot \sigma_{vp}(E) dE$$

▶ To detect *N* > 10 neutrinos, we need

 $V_{\rm det}$  > 1 km<sup>3</sup>

The need for km-scale detectors

  - $V_{\rm eff} \sim 1 \, \rm km^3 \, (> 1 \, \rm PeV)$
- ▶ 86 strings, 5000+ OMs
- Sees high-energy
- astrophysical v

#### OM: optical module

#### Baikal NT200+

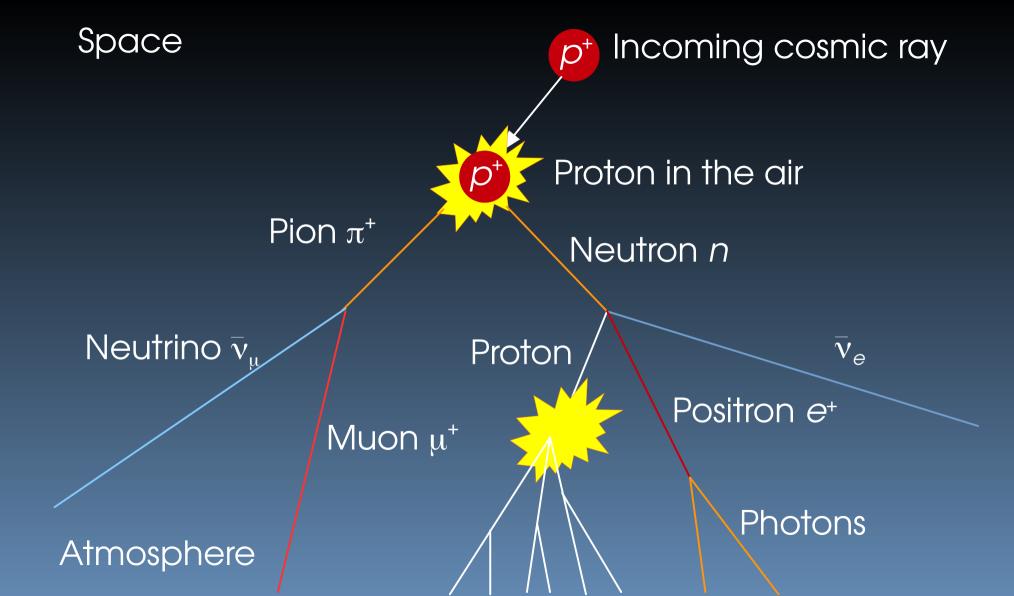

- Lake Baikal
- Completed 1998 (upgraded 2005)
- $V_{\rm eff} \sim 10^{-4} \, {\rm km}^3 \, (10 \, {\rm TeV})$ 
  - $V_{\rm eff} \sim 0.01 \, {\rm km^3} \, (10 \, {\rm PeV})$
- ▶ 8 strings, 192+ OMs

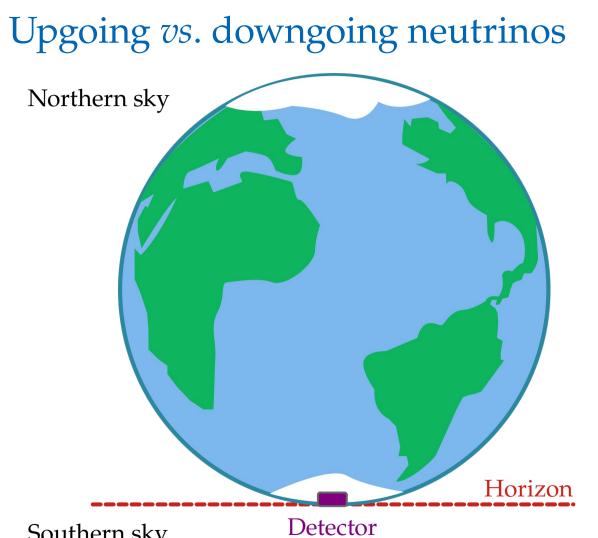

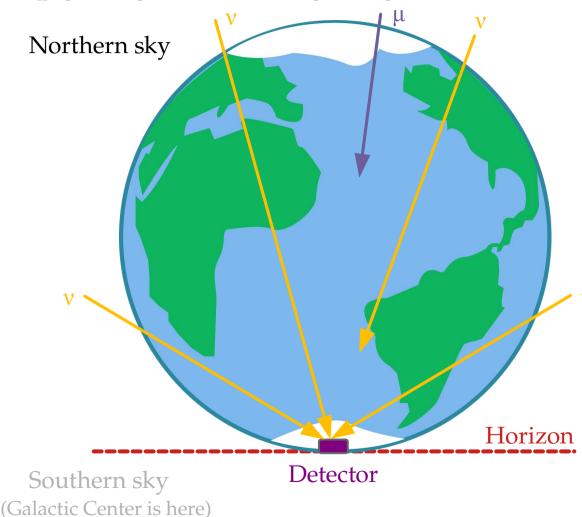

NORMAL "ASTRONOMER NEUTRINO ASTRONOMER IJ 5 .

Southern sky (Galactic Center is here)

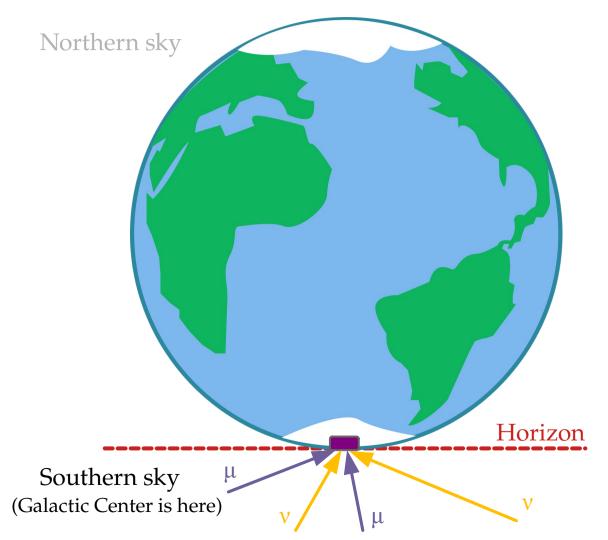

### Upgoing vs. downgoing neutrinos

Neutrinos from the Northern sky ≡ Upgoing neutrinos

- Atmospheric muons stopped
- Dominated by atmospheric v
- High-energy v flux attenuated
- High statistics
- Good for finding sources with through-going muon tracks

### Downgoing vs. upgoing neutrinos

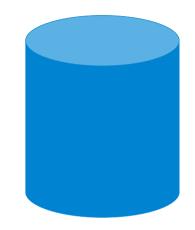

Neutrinos from the Southern sky ≡ Downgoing neutrinos

- Need to mitigate atmospheric muons and v:
  - Use higher-energy events
  - ► Use starting a self-veto
- Dominated by astrophysical v (after event selection)
- Low statistics
- Good for measuring the diffuse flux of astrophysical v

Neutrino source

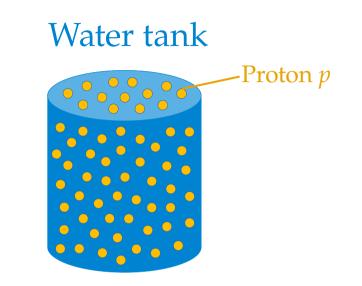

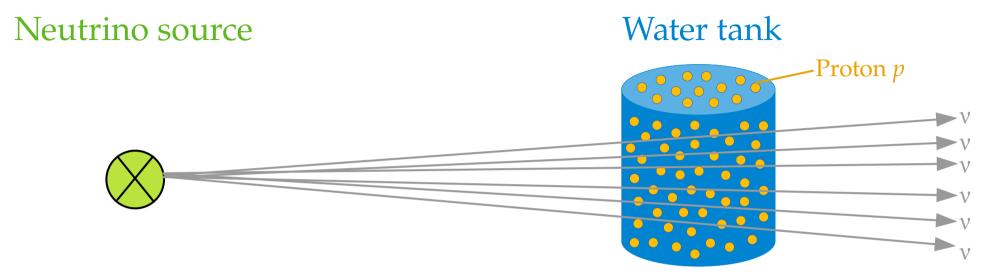

#### Water tank

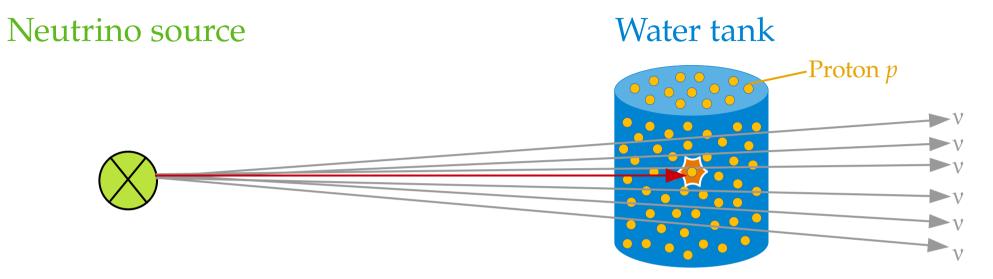

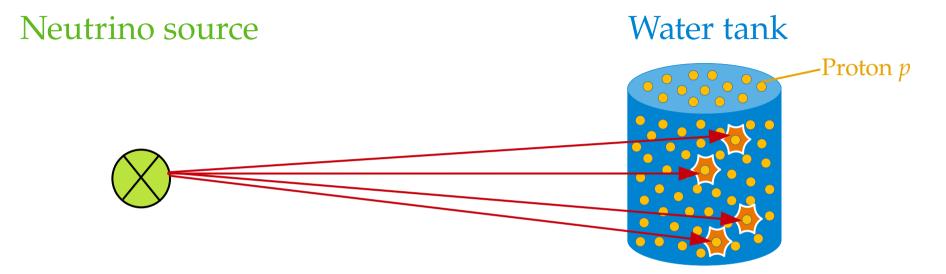

Neutrino source

 $\frac{\text{Number of}}{\text{interacting }v} =$ 

 $\frac{\text{Number of}}{\text{interacting }v} = \frac{\text{Chance that one }v}{\text{interacts with one }p}$ 

Number of interacting v

Chance that one v interacts with one p

Fixed by Nature (weak interactions): *neutrino-proton cross section* 

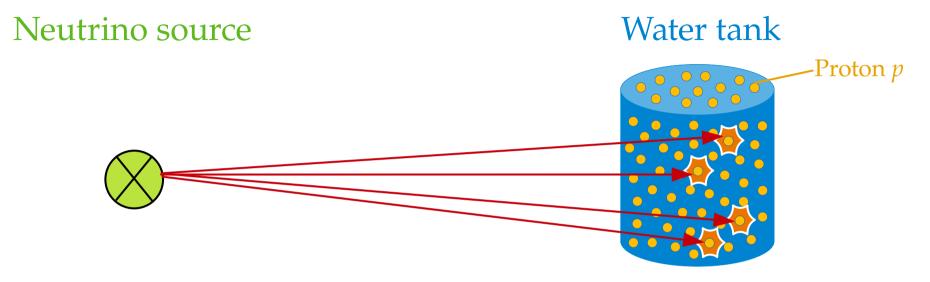

Number of interacting v

Chance that one v interacts with one *p* 

× Number of v that reach the tank

Fixed by Nature (weak interactions): *neutrino-proton cross section* 

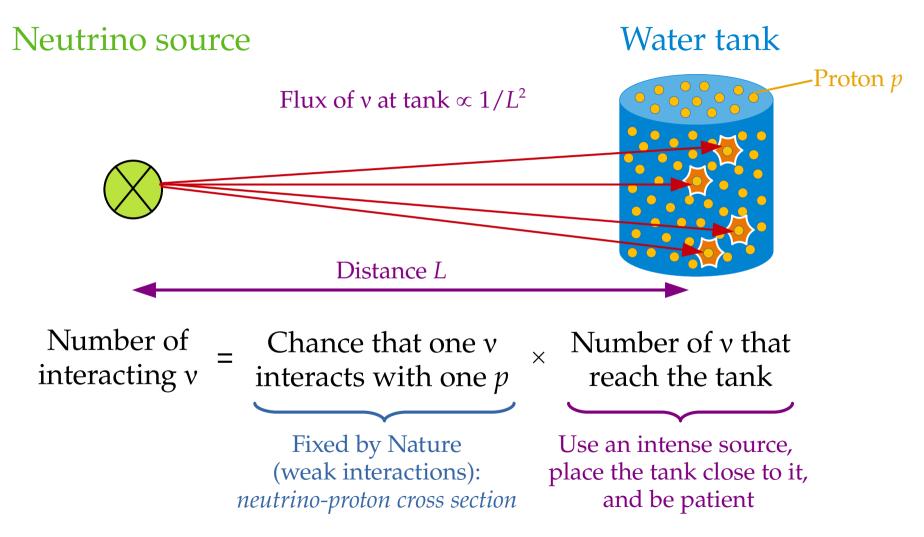

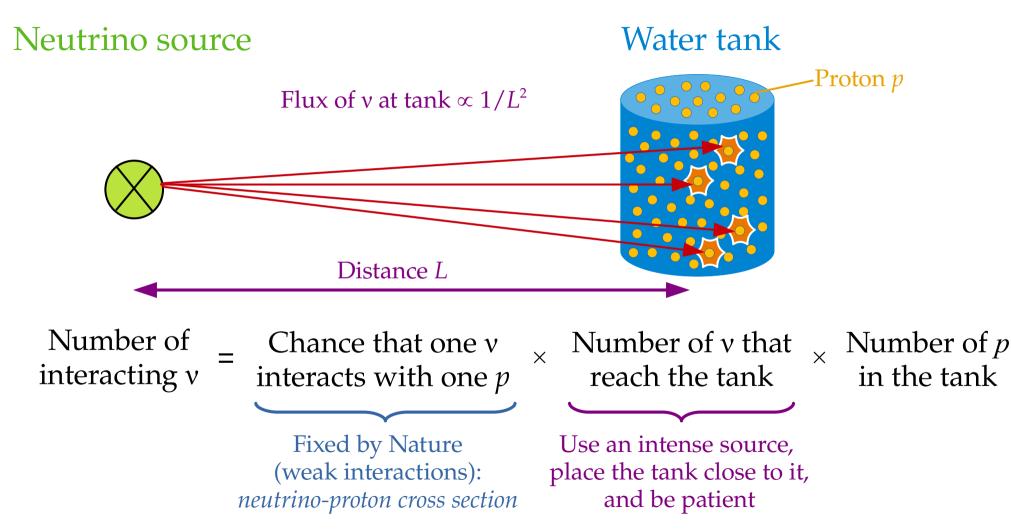

Number of interacting v

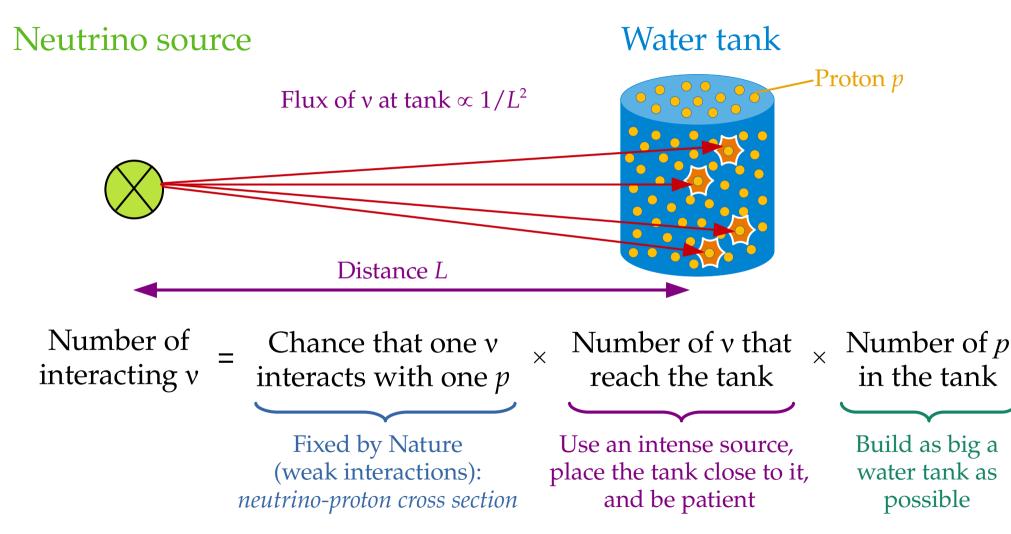

Chance that one v interacts with one *p* 

 Number of v that reach the tank

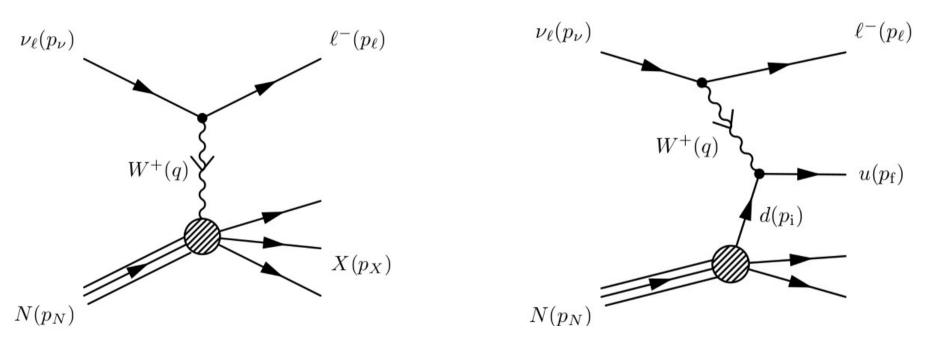

Fixed by Nature (weak interactions): *neutrino-proton cross section*  Use an intense source, place the tank close to it, and be patient

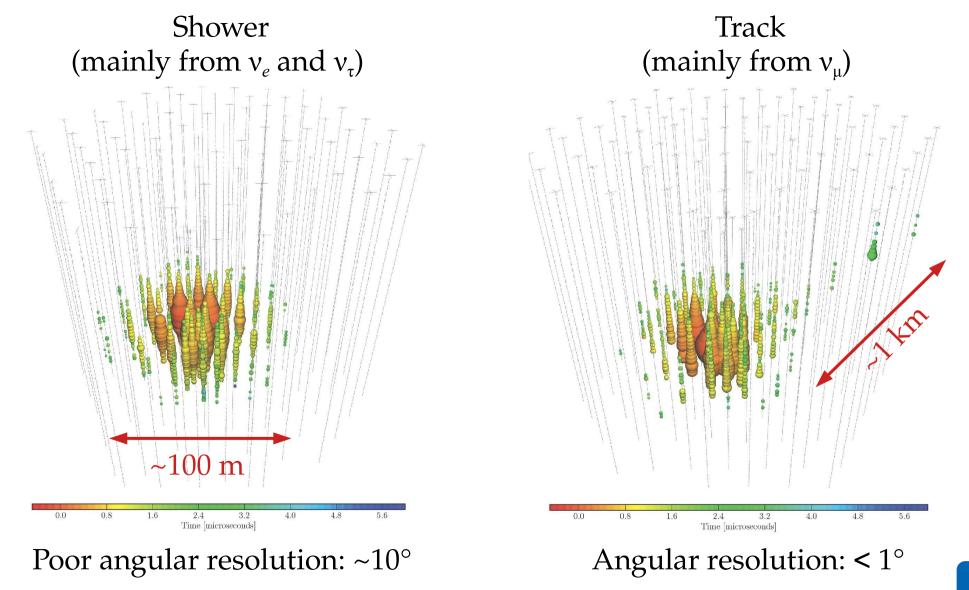

# Neutrino-nucleon deep inelastic scattering What you see Beneath the hood

(Plus the equivalent neutral-current process (Z-exchange))

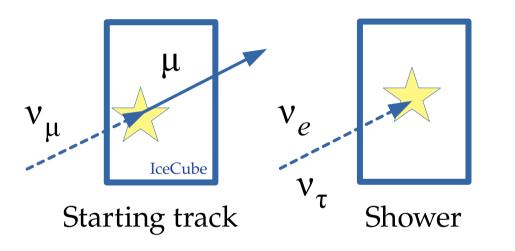

Giunti & Kim, Fundamentals of Neutrino Physics & Astrophysics

### Contained vs. uncontained events

### Contained events

### Through-going muons

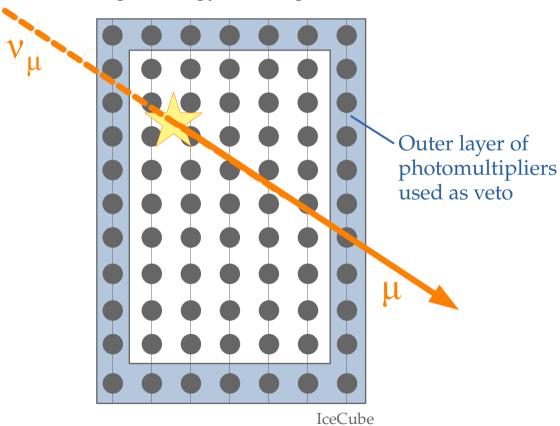

**Pro:** Clean determination of  $E_v$ **Con:** Few events (~100 in 10 yr) ν<sub>μ</sub> Through-going muon **Pro:** Lots of events (few 100k)

**Con:** Uncertain estimates of  $E_v$ 

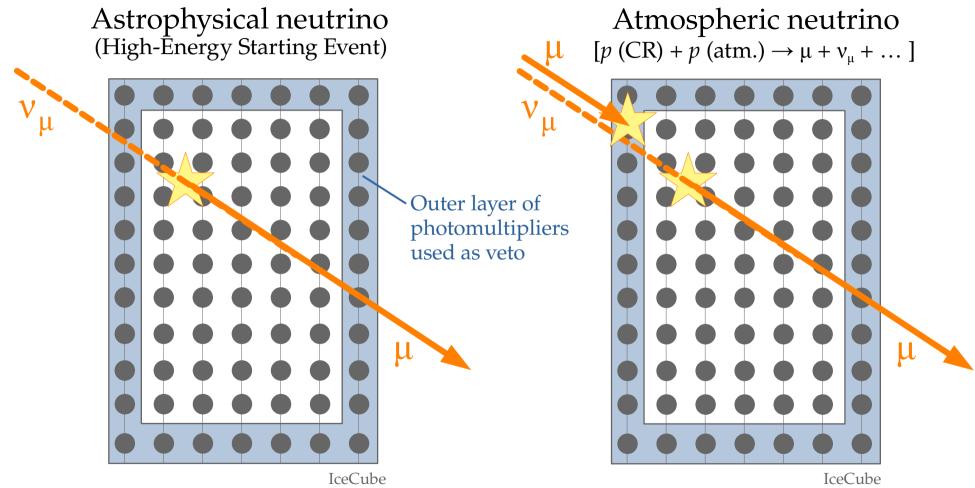

### IceCube self-veto: High-Energy Starting Events (HESE)

hergy s

Arrival Oline CLIONS

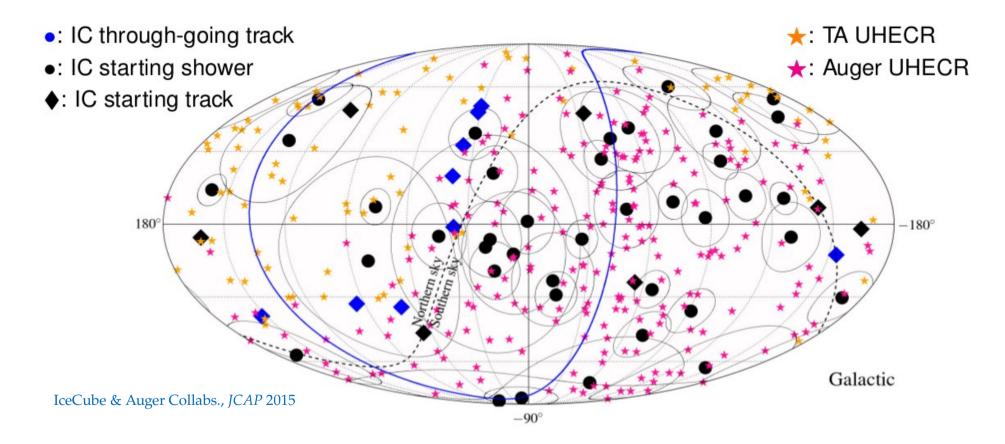

**Standard expectation:** and γ from transients arrive simultaneously **Standard expectation:** Equal number of  $v_e$ ,  $v_{\mu}$ ,  $v_{\tau}$ 

## Arrival directions (7.5 yr)

No significant excess in the neutrino sky map:

## Neutrino–UHECR angular correlation?

No significant correlation with UHECRs ( $<3.3\sigma$ )

#### A null neutrino-UHECR correlation makes sense

UHECRs trace sources within  $\lambda_{GZK} \approx 100 \text{ Mpc}$ 

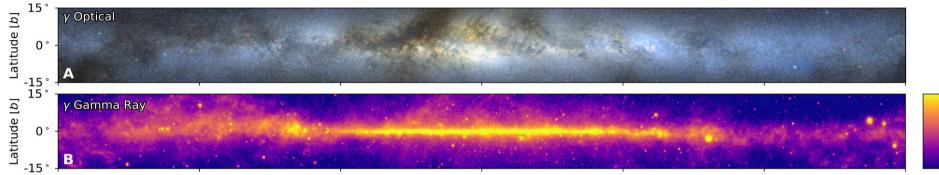

Neutrinos come from anywhere inside the Hubble horizon  $D_{\rm H} \approx 4 \, {\rm Gpc}$ 

So the maximum possible correlation is  $\frac{\lambda_{\rm GZK}}{D_{\rm H}} \approx 2.5\%$ 

Current number of IceCube high-energy starting tracks (HESE): ~100

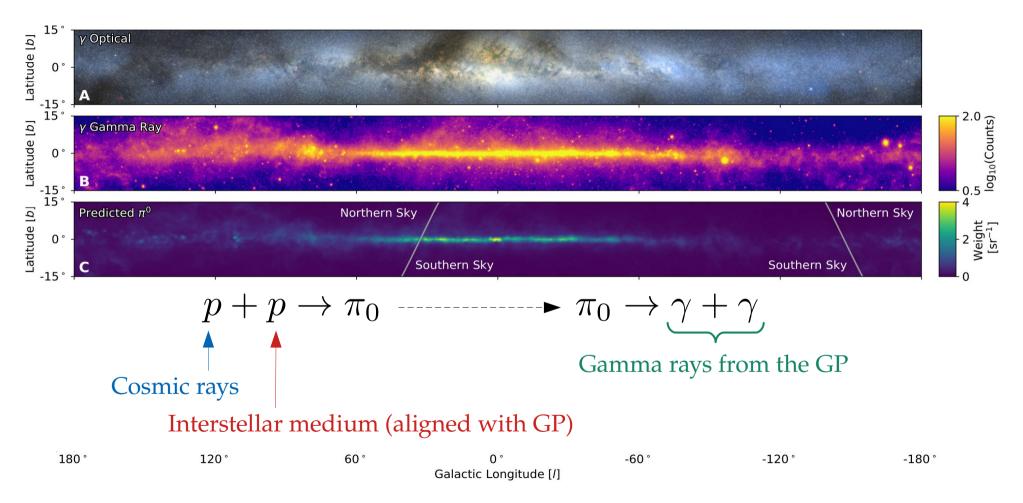

: Expected UHECR correlation with only ~3 neutrinos

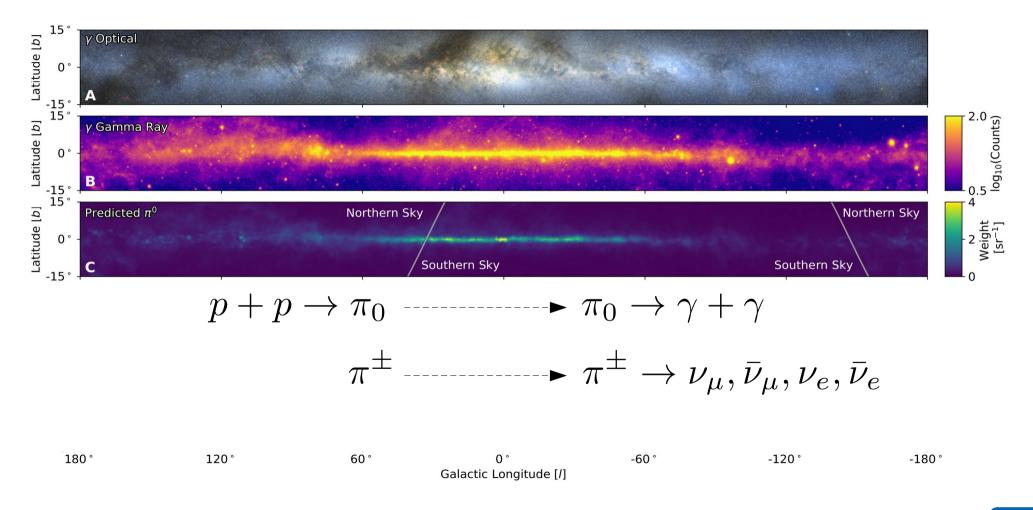

(Also, potential correlation is weakened by magnetic deflection, angular resolution, etc.)

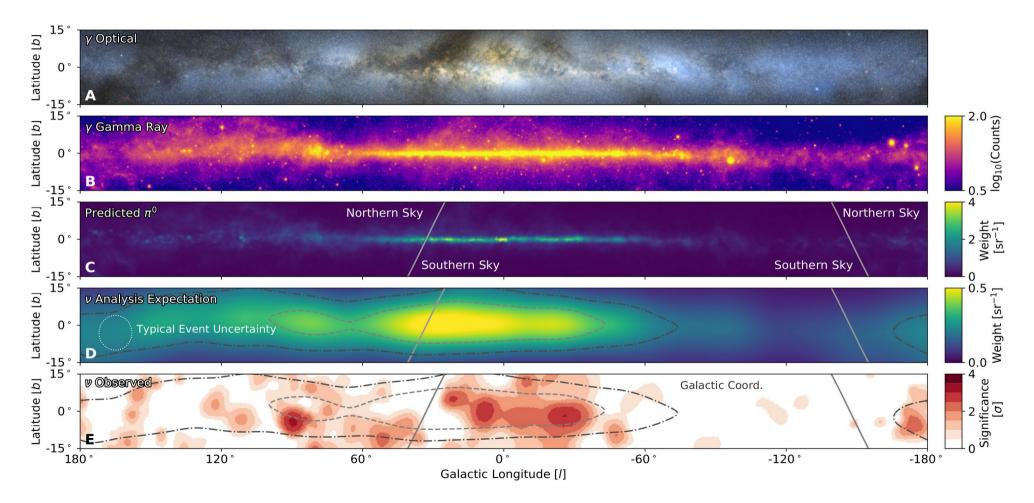

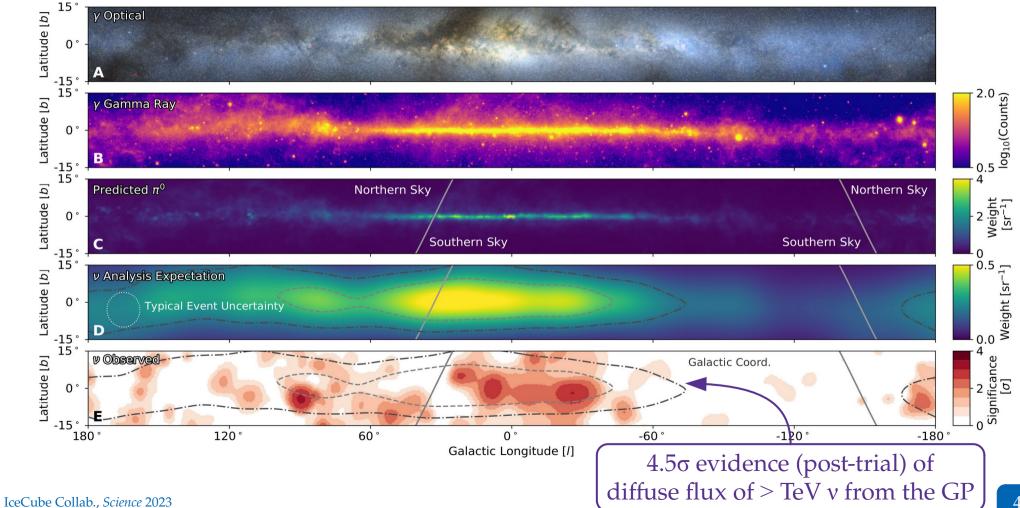

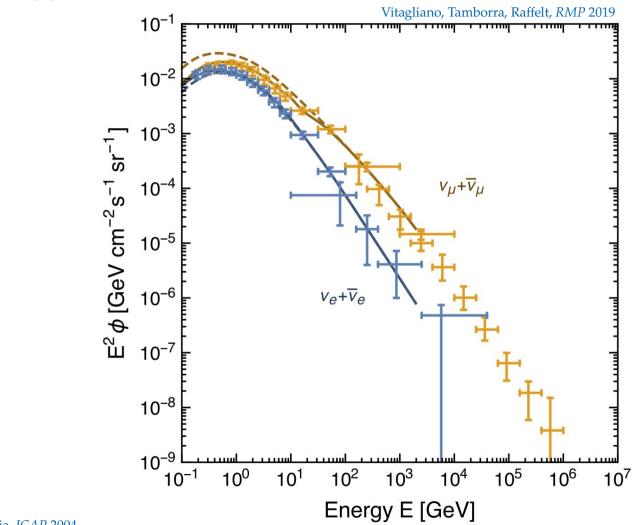

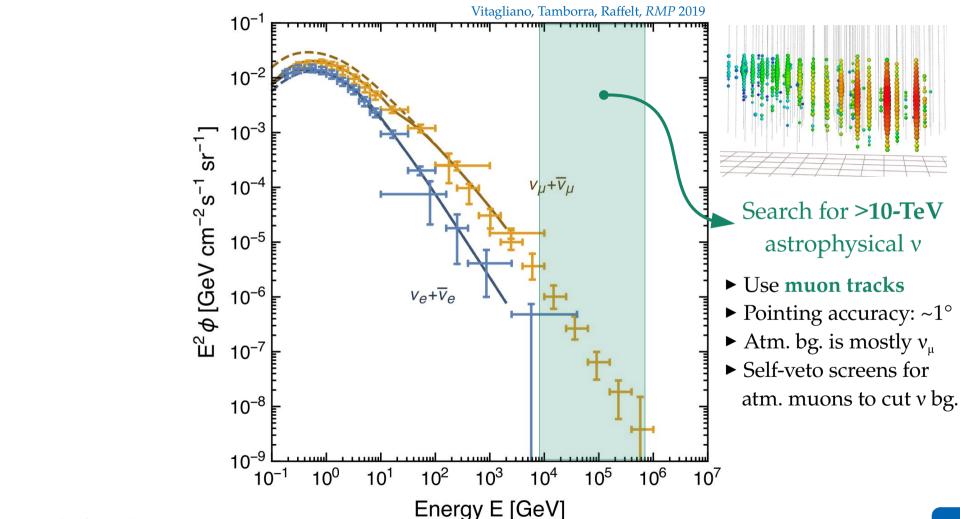

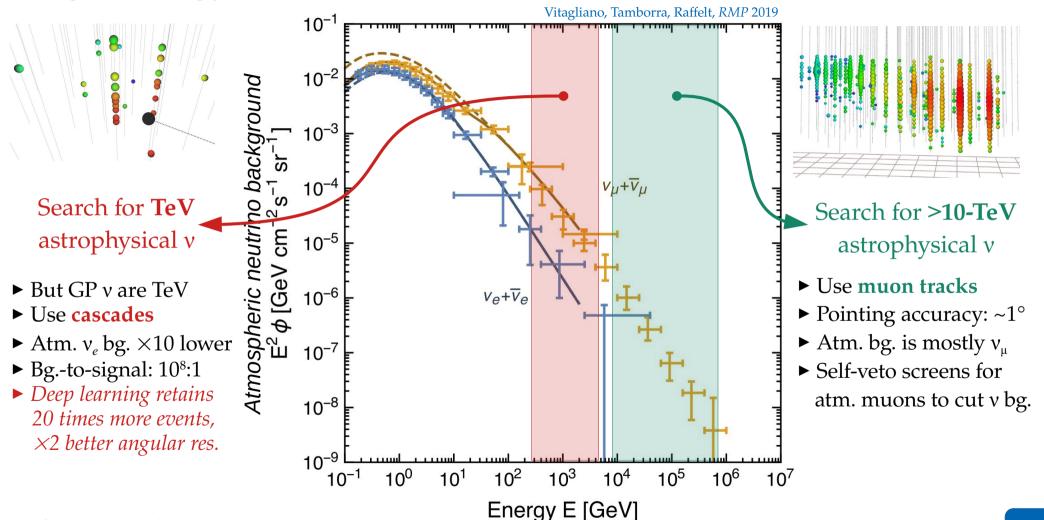

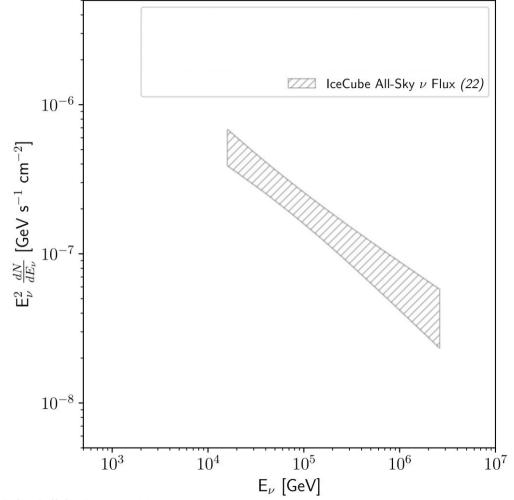

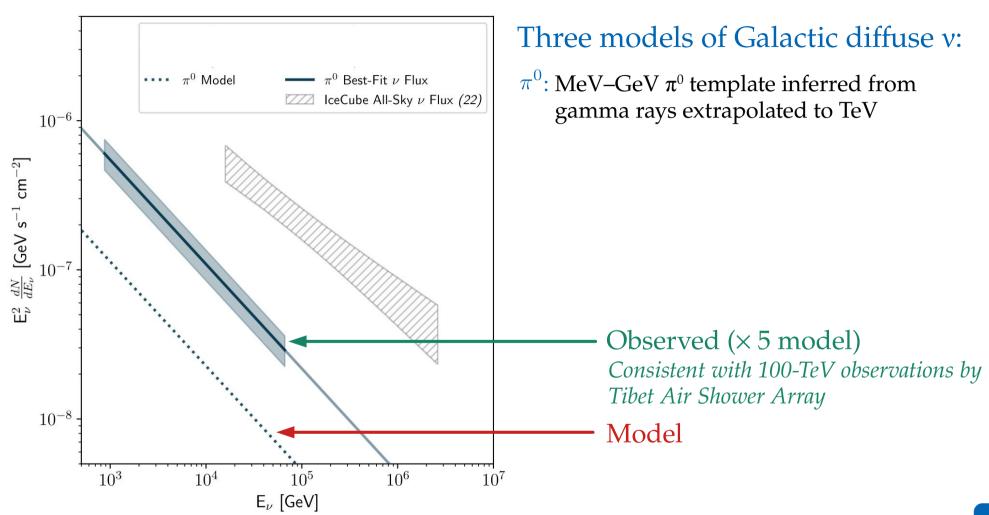

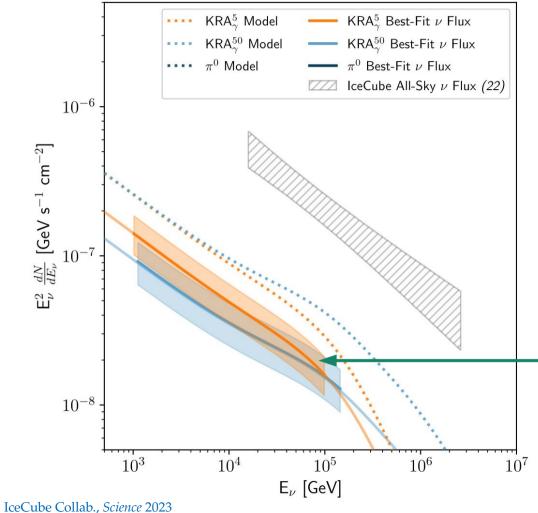

IceCube Collab., Science 2023

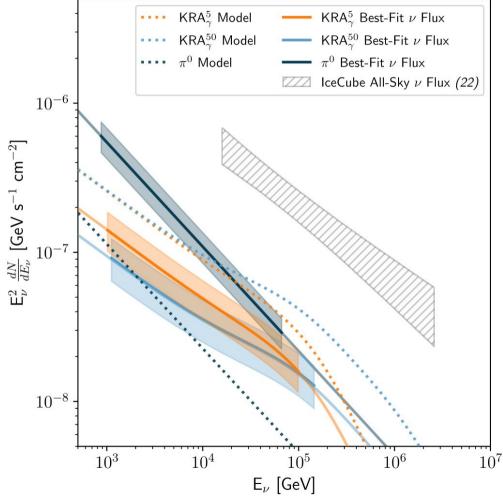

#### Three models of Galactic diffuse v:

 $\pi^0$ : MeV–GeV  $\pi^0$  template inferred from gamma rays extrapolated to TeV

 $KRA_{\gamma}^{5}$ : Spectrum varies spatially, harder v spectrum, cut-off at 5 PeV in CR energy  $KRA_{\gamma}^{50}$ : Cut-off at 50 PeV in CR energy

> Observed ( $\times 0.5$  model) *Cut-off energy could be different from the* 5 and 50 PeV tested

#### Three models of Galactic diffuse v:

 $\pi^0$ : MeV–GeV  $\pi^0$  template inferred from gamma rays extrapolated to TeV

 $\mathrm{KRA}_{\gamma}^{5}$ : Spectrum varies spatially, harder v spectrum, cut-off at 5 PeV in CR energy  $\mathrm{KRA}_{\gamma}^{50}$ : Cut-off at 50 PeV in CR energy

None of the models matched data (caveat: there are relatively simple models)

No Galactic v source identified (likely diffuse + source: Fang & Murase, 2307.02905)

GP flux is 6–13% of all-sky at 30 TeV

**Standard expectation:** Power-law energy spectrum **Standard expectation:** Isotropy (for diffuse flux)

Standard expectation: v and γ from transients arrive simultaneously

**Standard expectation:** Equal number of  $v_e$ ,  $v_{\mu}$ ,  $v_{\tau}$

A neutrino is created with *one* definite flavor, *e.g.*,

## ν<sub>e</sub>

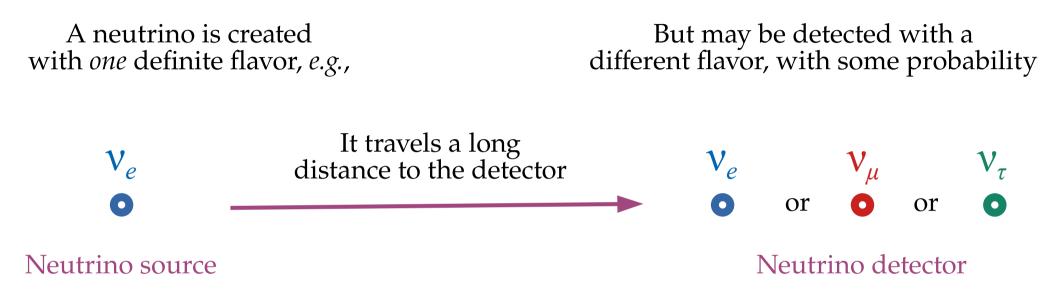

Neutrino source

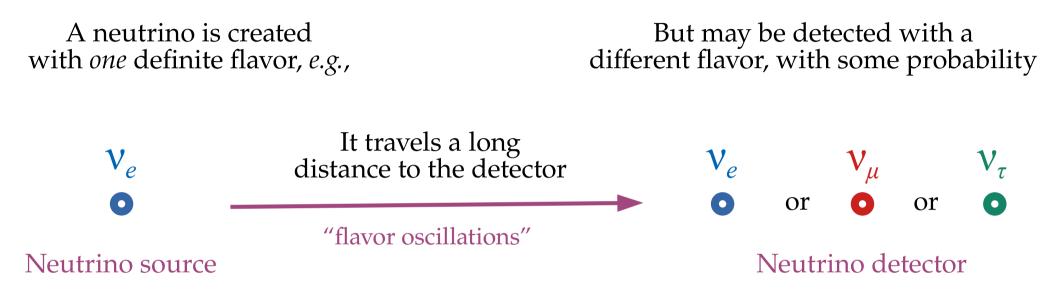

A neutrino is created with *one* definite flavor, *e.g.*,

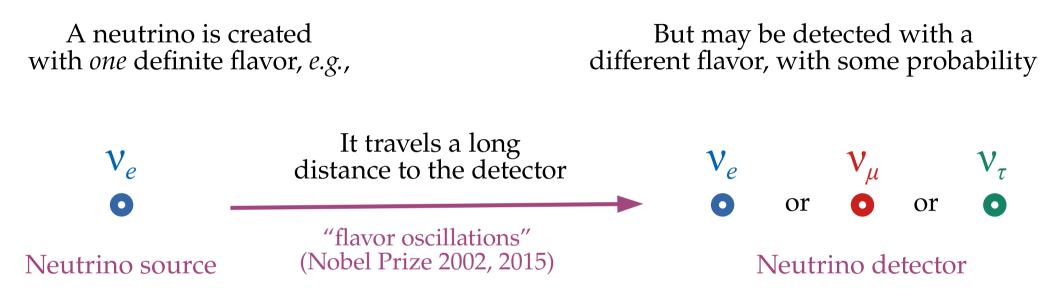

It travels a long distance to the detector

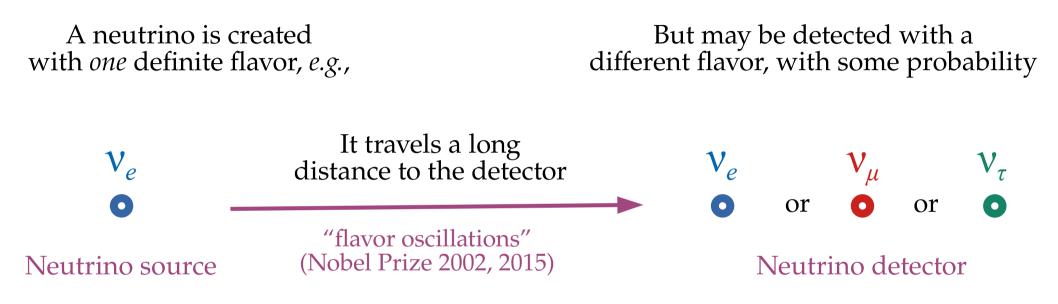

Neutrino source

 $v_e$ 

We use quantum mechanics to compute probabilities over *macroscopic* distances!

#### Flavor-transition probability: the quick and dirty of it

In matrix form: 
$$\begin{pmatrix} \nu_e \\ \nu_\mu \\ \nu_\tau \end{pmatrix} = \begin{pmatrix} U_{e1}^* & U_{e2}^* & U_{e3}^* \\ U_{\mu 1}^* & U_{\mu 2}^* & U_{\mu 3}^* \\ U_{\tau 1}^* & U_{\tau 2}^* & U_{\tau 3}^* \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \\ \nu_3 \end{pmatrix}$$

▶ Pontecorvo-Maki-Nakagawa-Sakata matrix ( $c_{ij} = \cos \theta_{ij}, s_{ij} = \sin \theta_{ij}$ ):

$$U = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{pmatrix} \begin{pmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13} \end{pmatrix} \begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} e^{i\alpha_1/2} & 0 & 0 \\ 0 & e^{i\alpha_2/2} & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
  
Atmospheric Cross mixing Solar Majorana CP phases  
Probability for  $\mathbf{v}_{\alpha} \rightarrow \mathbf{v}_{\beta}$ :  $P_{\nu_{\alpha} \rightarrow \nu_{\beta}} = \delta_{\alpha\beta} - 4 \sum_{i>j} \operatorname{Re}(U_{\alpha i}^{*}U_{\beta i}U_{\alpha j}U_{\beta j}^{*}) \sin^{2}\left(\Delta m_{ij}^{2}\frac{L}{4E}\right) + 2 \sum_{i>j} \operatorname{Im}(U_{\alpha i}^{*}U_{\beta i}U_{\alpha j}U_{\beta j}^{*}) \sin\left(\Delta m_{ij}^{2}\frac{L}{2E}\right)$ 

#### Flavor-transition probability: the quick and dirty of it

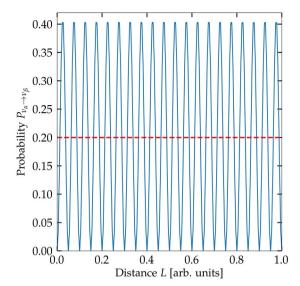

• In matrix form: 
$$\begin{pmatrix} \nu_e \\ \nu_\mu \\ \nu_\tau \end{pmatrix} = \begin{pmatrix} U_{e1}^{e1} & U_{e2}^{e2} & U_{e3}^{e3} \\ U_{\mu1}^{e1} & U_{\mu2}^{e2} & U_{\mu3}^{e3} \\ U_{\tau1}^{e2} & U_{\tau3}^{e3} \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \\ \nu_3 \end{pmatrix} = \begin{pmatrix} \theta_{23} \approx 48^{\circ} \\ \theta_{13} \approx 9^{\circ} \\ \theta_{13} \approx 9^{\circ} \\ \theta_{12} \approx 34^{\circ} \\ \delta \approx 222^{\circ} \end{pmatrix}$$
• Pontecorvo-Maki-Nakagawa-Sakata matrix ( $c_{ij} = \cos \theta_{ij}$ ,  $s_{ij} = \sin \theta_{ij}$ ):  

$$U = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{pmatrix} \begin{pmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13} \end{pmatrix} \begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} e^{i\alpha_1/2} & 0 & 0 \\ 0 & e^{i\alpha_2/2} & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
Atmospheric Cross mixing Solar Majorana CP phases
• Probability for  $\mathbf{v}_{\alpha} \rightarrow \mathbf{v}_{\beta}$ :  $P_{\nu_{\alpha} \rightarrow \nu_{\beta}} = \delta_{\alpha\beta} - 4 \sum_{i>j} \operatorname{Re}(U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin^2 \left( \Delta m_{ij}^2 \frac{L}{4E} \right) + 2 \sum_{i>j} \operatorname{Im}(U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin \left( \Delta m_{ij}^2 \frac{L}{2E} \right)$ 

#### ... But high-energy neutrinos oscillate *fast*

$$P_{\nu_{\alpha} \to \nu_{\beta}} = \delta_{\alpha\beta} - 4 \sum_{i>j} \operatorname{Re}(U_{\alpha i}^{*} U_{\beta i} U_{\alpha j} U_{\beta j}^{*}) \sin^{2} \left(\Delta m_{ij}^{2} \frac{L}{4E}\right) + 2 \sum_{i>j} \operatorname{Im}(U_{\alpha i}^{*} U_{\beta i} U_{\alpha j} U_{\beta j}^{*}) \sin\left(\Delta m_{ij}^{2} \frac{L}{2E}\right)$$

Oscillation length for 1-TeV v:  $2\pi \times 2E/\Delta m^2 \sim 0.1$  pc

~ 8% of the way to Proxima Centauri
≪ Distance to Galactic Center (8 kpc)
≪ Distance to Andromeda (1 Mpc)

≪ Cosmological distances (few Gpc)

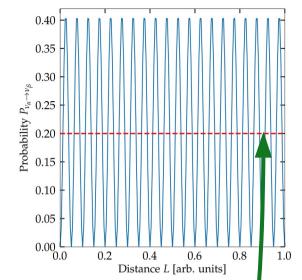

We cannot resolve oscillations, so we use instead the average probability:

$$\left\langle P_{\nu_{\alpha} \to \nu_{\beta}} \right\rangle = \sum_{i=1}^{3} \left| U_{\alpha i} \right|^2 \left| U_{\beta i} \right|^2$$

### ... But high-energy neutrinos oscillate *fast*

$$P_{\nu_{\alpha} \to \nu_{\beta}} = \delta_{\alpha\beta} - 4 \sum_{i>j} \operatorname{Re}(U_{\alpha i}^{*} U_{\beta i} U_{\alpha j} U_{\beta j}^{*}) \sin^{2} \left(\Delta m_{ij}^{2} \frac{L}{4E}\right) + 2 \sum_{i>j} \operatorname{Im}(U_{\alpha i}^{*} U_{\beta i} U_{\alpha j} U_{\beta j}^{*}) \sin \left(\Delta m_{ij}^{2} \frac{L}{2E}\right)$$

Oscillation length for 1-TeV v:  $2\pi \times 2E/\Delta m^2 \sim 0.1$  pc

~ 8% of the way to Proxima Centauri

Similar to the evolution of cosmology to a high-precision field in the 1990s

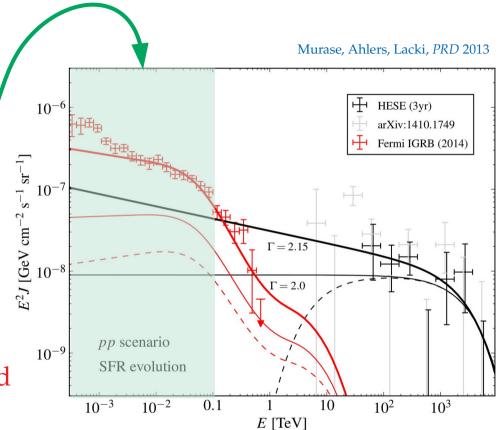

Made robust and meaningful by accounting for all relevant particle and astrophysics uncertainties Backup slides

#### Three Strategies to Reveal Sources Using TeV–PeV v

# Constraints from the gamma-ray background

- Production via *pp*: v and gamma-ray spectra follow the CR spectrum E<sup>-Γ</sup>
- Gamma-ray interactions on the CMB make them pile up at GeV
- ► *Fermi* gamma-ray background is not exceeded only if  $\Gamma < 2.2$
- ► But IceCube found  $\Gamma = 2.5-2.7$
- Therefore, production via *pp* is disfavored between 10–100 TeV

#### Using high-energy neutrinos as magnetometers

If sources have strong magnetic fields, charged particles cool via synchrotron:

$$p + \gamma_{\text{target}} \rightarrow \Delta^{+} \rightarrow \begin{cases} p + \pi^{0}, \text{ Br} = 2/3 \\ n + \pi^{+}, \text{ Br} = 1/3 \end{cases}$$

$$\pi^{0} \rightarrow \gamma + \gamma$$

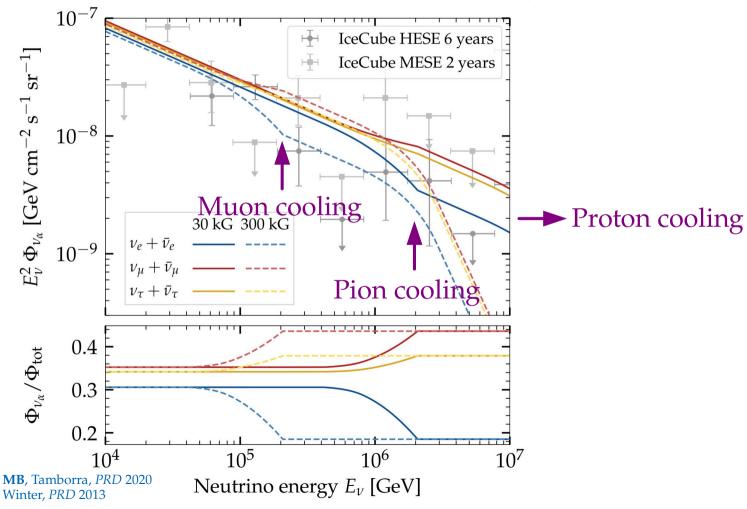

$$\pi^{+} \rightarrow \mu^{+} + \nu_{\mu} \rightarrow \bar{\nu}_{\mu} + e^{+} + \nu_{e} + \nu_{\mu}$$

$$n \text{ (escapes)} \rightarrow p + e^{-} + \bar{\nu}_{e}$$

## Bump-hunting in the diffuse flux of high-energy neutrinos Bump-like spectra can reveal the presence of v production via $p\gamma$ :

## Diffuse flux of neutrinos from GRBs

- ► How do we estimate it?
- Compute the expected v fluence from a sample of N<sub>obs</sub> observed GRBs
- ► Stack the fluences to obtain the total *F*<sub>v</sub>
- Quasi diffuse flux:

$$\phi_{\nu}(E_{\nu}) = F_{\nu}(E_{\nu}) \frac{1}{4\pi} \frac{1}{N_{\text{obs}}} \frac{667 \text{ bursts}}{\text{yr}}$$
(N<sub>obs</sub> = 117 in the plot)

## Are GRBs still good UHECR source candidates?

High-luminosity bursts: Not so much
Low-luminosity bursts: Yes!

	HL GRBs	LL GRBs
Luminosity (erg s <sup>-1</sup> )	> 10 <sup>49</sup>	< 10 <sup>49</sup>
Rate (Gpc <sup>-3</sup> yr <sup>-1</sup> )	1	300 (predicted)
Survival of heavy nuclei in jet?	Unlikely	Likely
Can explain IceCube v?	No	Yes

## Are GRBs still good UHECR source candidates?

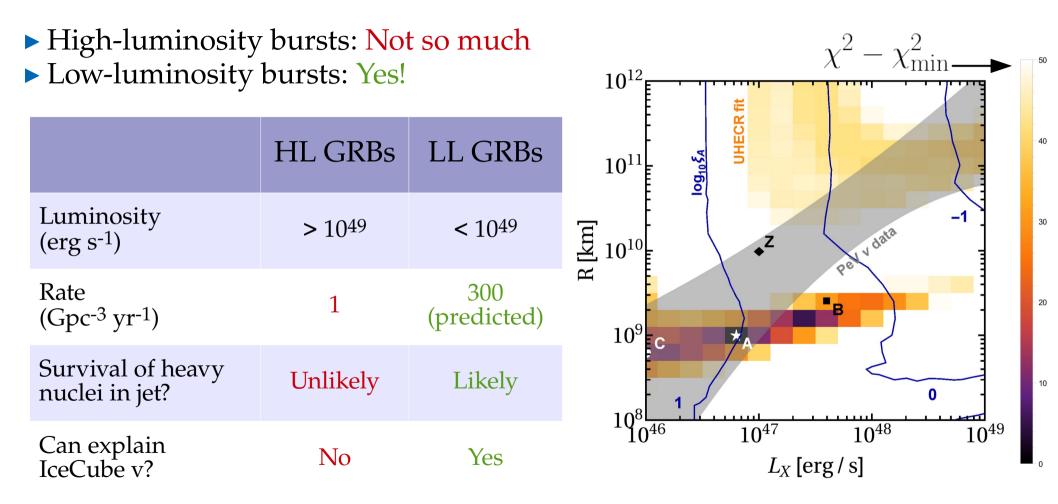

High-luminosity bursts: Not so much

Rate (Gpc <sup>-3</sup> yr <sup>-1</sup> )	1	300 (predicted)					
Survival of heavy nuclei in jet?	Unlikely	Likely					
Can explain IceCube v?	No	Yes					

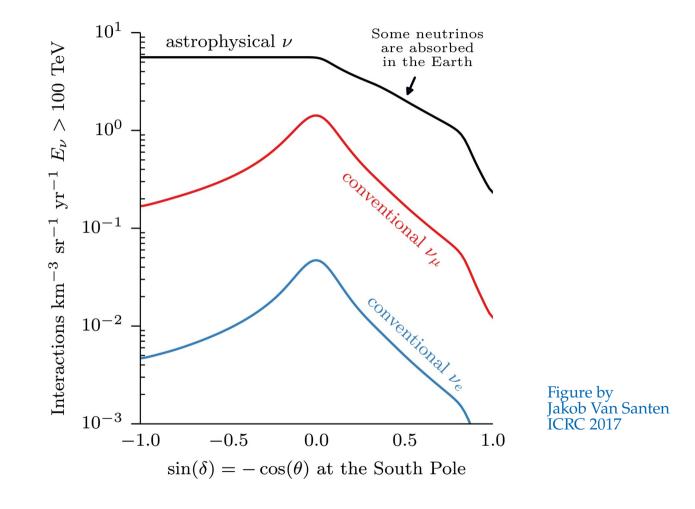

D. Boncioli, D. Biehl, & W. Winter, ApJ 2019; B.T. Zhang et al., PRD 2018

## Are GRBs still good UHECR source candidates?

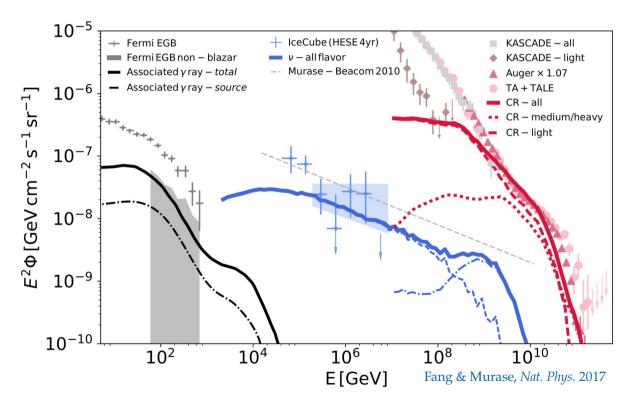

## Neutrino zenith angle distribution

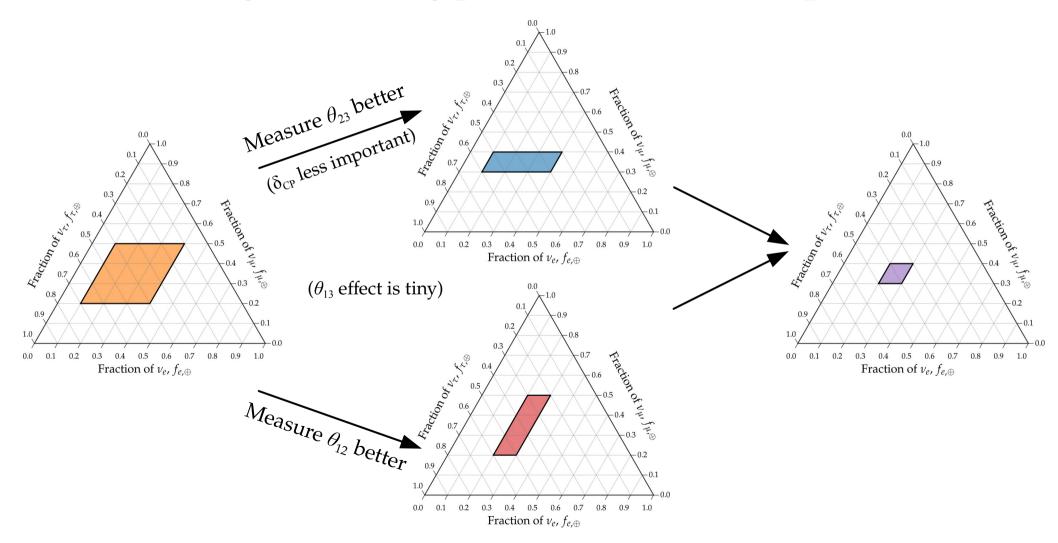

# Grand-unified v–UHECR–gamma-ray model

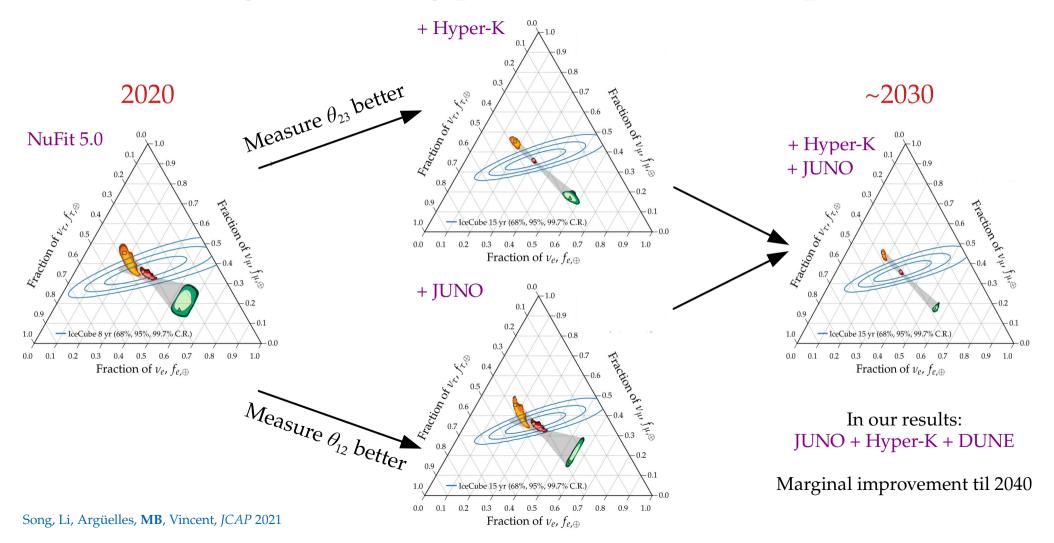

- Black-hole jets in galaxy clusters accelerate cosmic rays
- UHECRs make v and y in the magnetized cluster medium
- ► UHECRs above 0.1 EeV escape
- Consistent w/ observed
   UHECR
   spectrum, composition, isotropy
- Explains IceCube neutrinos
- Explains non-blazar Fermi EGB

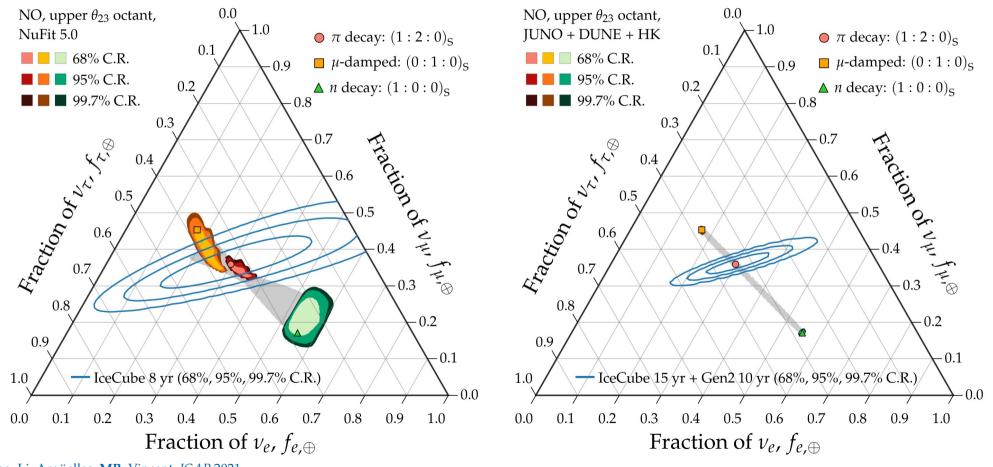

#### How knowing the mixing parameters better helps

## How knowing the mixing parameters better helps

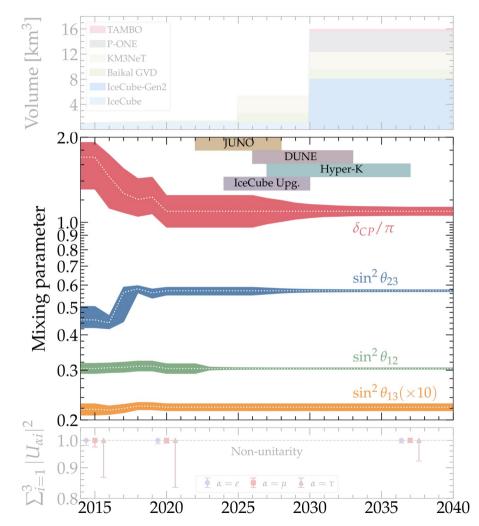

## Theoretically palatable regions: $2020 \rightarrow 2040$ 2020 2040

Song, Li, Argüelles, MB, Vincent, JCAP 2021

## How knowing the mixing parameters better helps

We can compute the oscillation probability more precisely:

$$f_{\alpha,\oplus} = \sum_{\beta=e,\mu,\tau} P_{\beta\alpha} f_{\beta,\mathrm{S}}$$

So we can convert back and forth between source and Earth more precisely

Theoretically palatable flavor regions  $\equiv MB, Beacom, Winter, PRL 2015$ Allowed regions of flavor ratios at Earth derived from oscillations

*Note:* The original palatable regions were frequentist [MB, Beacom, Winter, *PRL* 2015]; the new ones are Bayesian

## The Cosmogenic Neutrino Floor

Ahlers & Halzen, PRD 2012

- In a nucleus A of energy E, each nucleon has energy E/A
- Minimal cosmogenic v flux comes from maximizing nuclei survival
- *I.e.,* from minimizing *p* production from photo-disintegration
- v fluxes from UHECR nuclei (> 4 EeV) are presently beyond reach

Many TeV–EeV v telescopes in planning for 2020–2040
