

Discussion/Q&A: Search for LIV at DØ

- Introduction
- Relevant Differences
- Event Selection
- Uncertainties
- Results

Additional Questions: lumi

→ Time-dependency of luminosity measurement into 12 bins

→ Differences on the order of relative $\sim 10\%$

What is the time stamp and its resolution:

- Beginning and end of a lumi block, resolution is ~ 1 minute, use mid-point
- Uncertainty ± 30 s for such a “time stamp”
- Binning choice of 12 owed to limited statistics

[CERN Courier: Tevatron Legacy](#)

Additional Questions: toys

- Toy studies use 100k events sampled into 610 signal evts (5.3/fb) for a total of 1000 toy MC sets (re-use event factor $\leq 1\%$)
- Inject a SME signal of: $c_{\mu\nu} = (c_R)_{\mu\nu} + (c_L)_{\mu\nu} = 0.4$
- Binned into the 12 sidereal time bins

- Find mean of 0.41 on coefficient itself and σ of 0.99 with 0.13 ± 0.03
- Within statistical power of toy set: method works.
