A massive satellite encounter

Could a recent (≤ 100 Myr) and close (≤ 100 kpc) approach of a massive satellite significantly impact the dark matter (DM) distribution in the Solar neighborhood?

Gaia's EDR3 sky map. Credit: ESA/Gaia/DPAC

The Large Magellanic Cloud

The LMC is the most massive satellite of the Milky Way and likely on its first passage around the Galaxy.

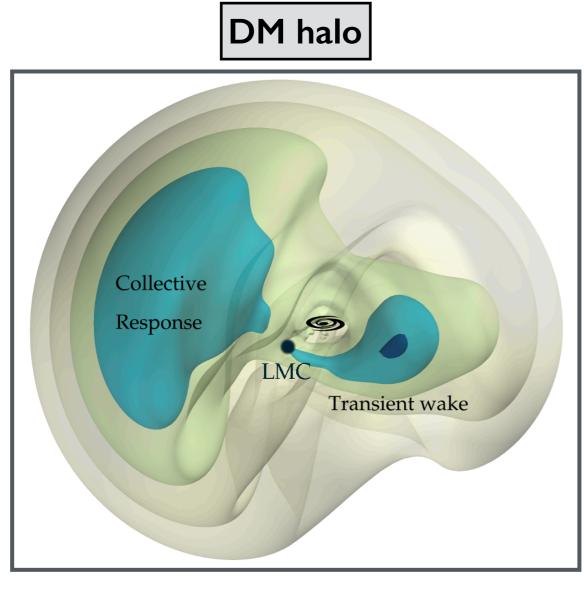

Gaia's EDR3 sky map. Credit: ESA/Gaia/DPAC

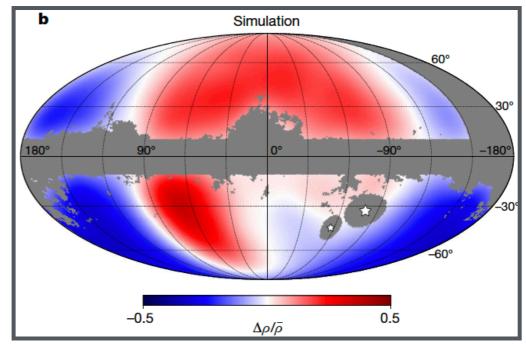

LMC

The effect of the LMC

The LMC introduces perturbations in the DM and stellar halo.

Garavito-Camargo et al, ApJ 919, 2, 109 (2021) Garavito-Camargo et al, ApJ 884, 51 (2019)

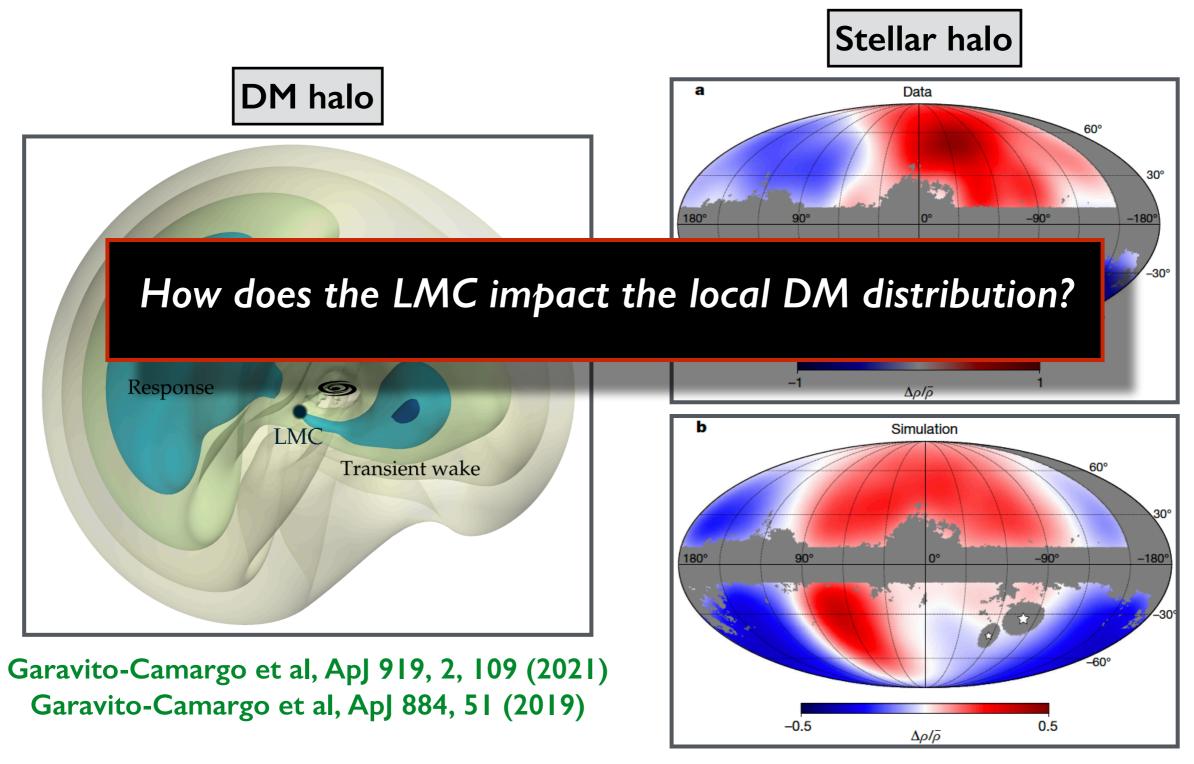

Conroy et al, Nature 592, 534–536 (2021)

Stellar halo

The effect of the LMC

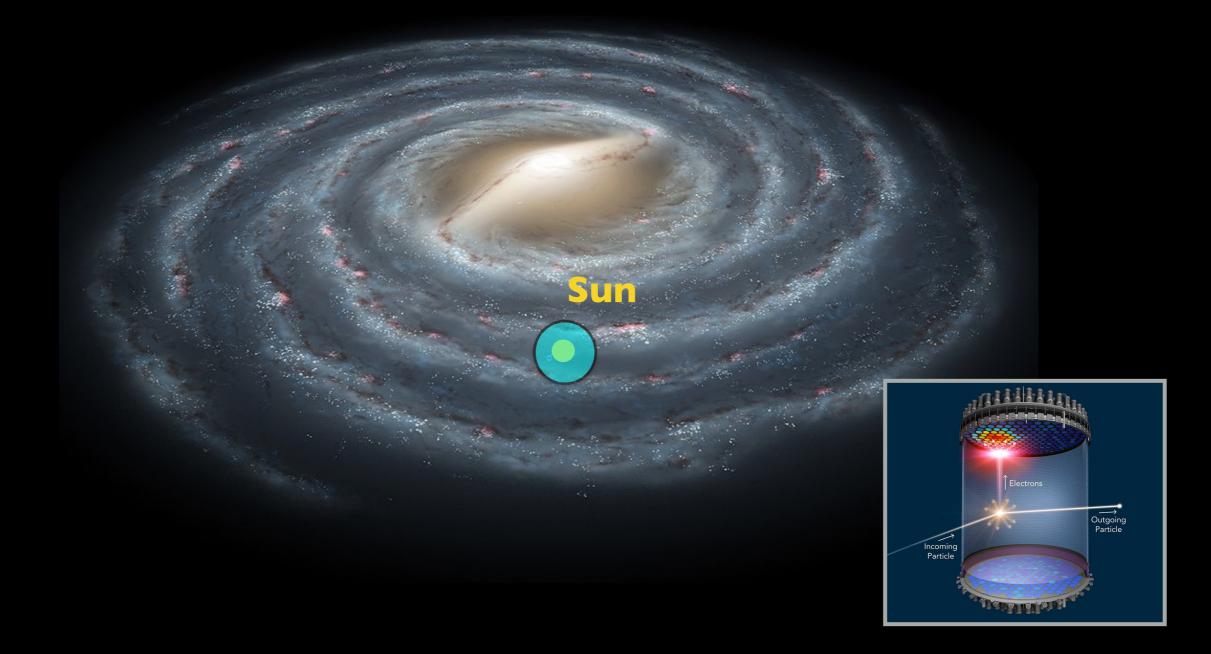

The LMC introduces perturbations in the DM and stellar halo.

Conroy et al, Nature 592, 534–536 (2021)

Local dark matter distribution

Signals in direct DM searches strongly depend on the DM distribution in the Solar neighborhood.

Direct detection event rate

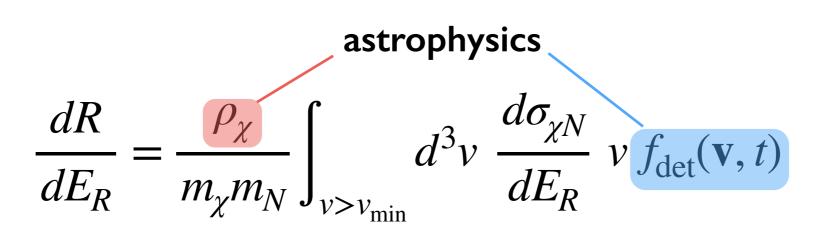

• The differential event rate (per unit detector mass):

$$\frac{dR}{dE_R} = \frac{\rho_{\chi}}{m_{\chi}m_N} \int_{v > v_{\min}} d^3v \ \frac{d\sigma_{\chi N}}{dE_R} \ v \ f_{det}(\mathbf{v}, t)$$

 $v_{\min} = \sqrt{m_N E_R / (2\mu_{\chi N}^2)}$: minimum DM speed required to produce a recoil energy E_R .

Direct detection event rate

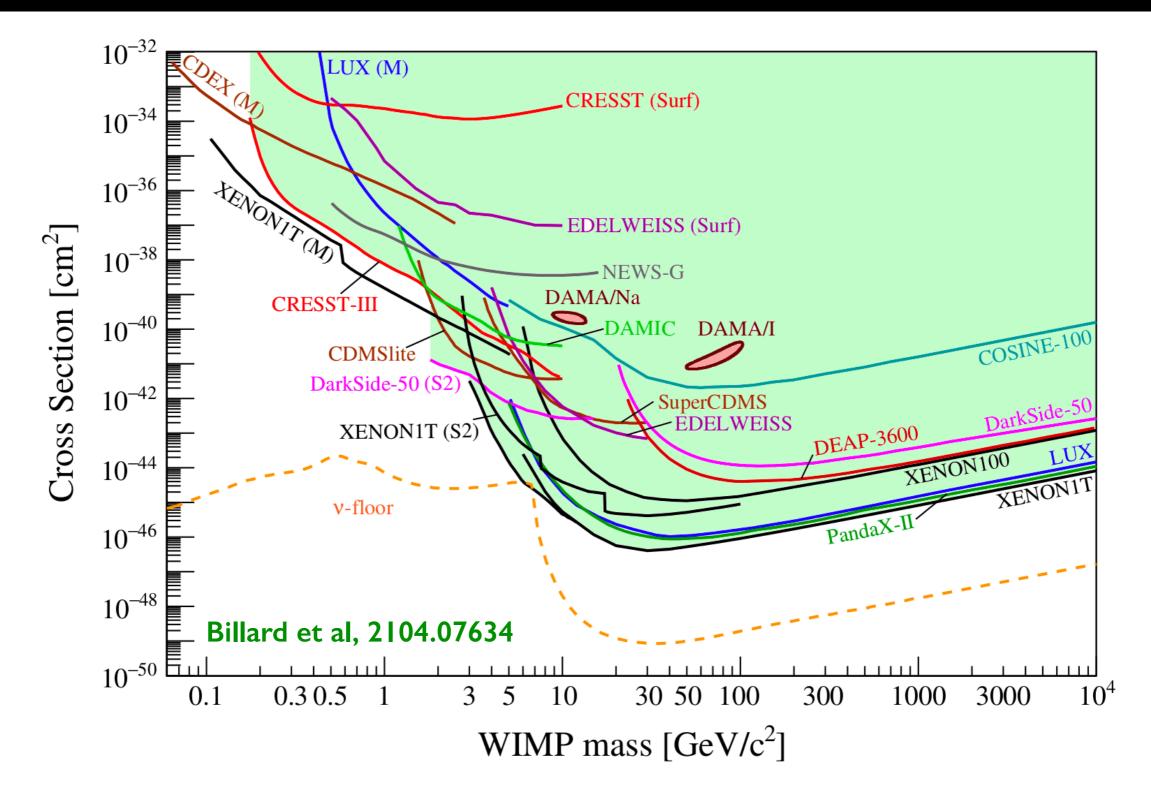

• The differential event rate (per unit detector mass):

 $v_{\min} = \sqrt{m_N E_R / (2\mu_{\chi N}^2)}$: minimum DM speed required to produce a recoil energy E_R .

- Astrophysical inputs:
 - **local DM density:** *normalization in event rate.*
 - **local DM velocity distribution:** enters the event rate through an integration.

Direct detection limits

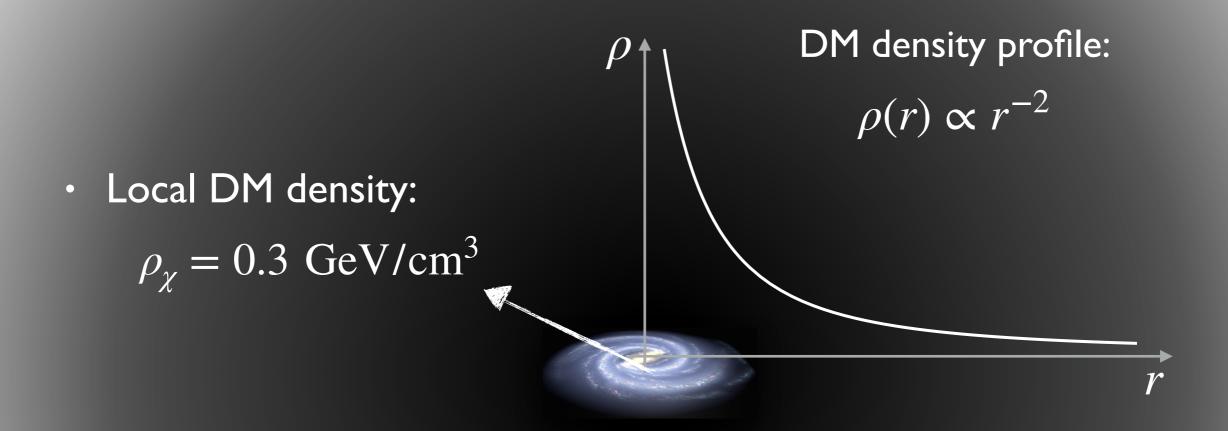

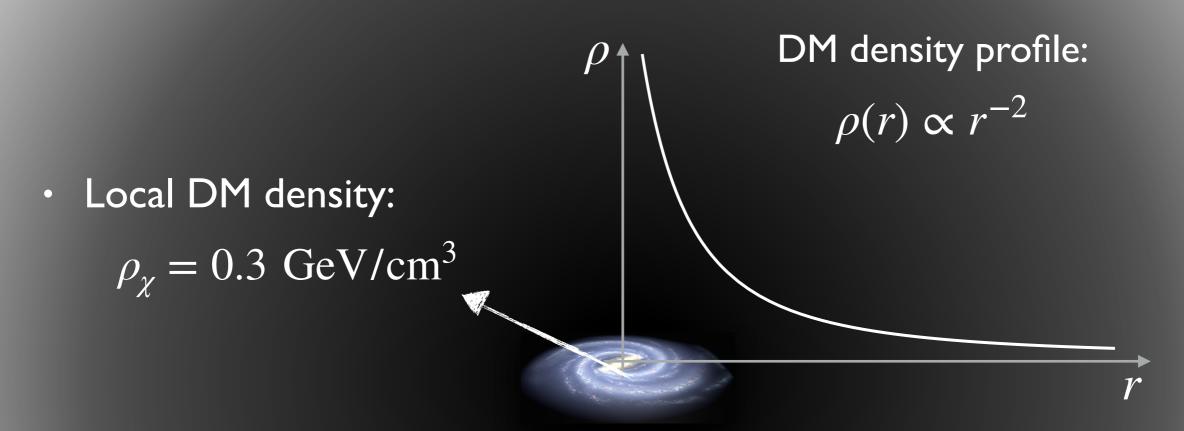

Assumption for the DM distribution: Standard Halo Model

 The simplest model for the DM distribution in our Galaxy is the Standard Halo Model (SHM): isothermal sphere with an isotropic Maxwell-Boltzmann velocity distribution.

Drukier, Freese, Spergel, 1986

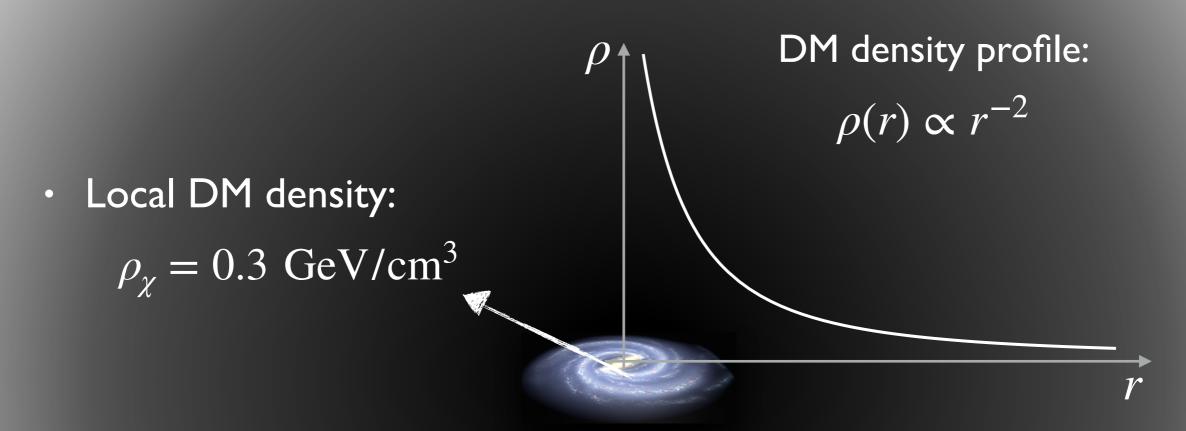

- Most probable DM speed: $v_c = 220 \text{ km/s}$
- Local DM velocity distribution:

$$f_{\text{gal}}(\mathbf{v}) = \begin{cases} N \exp\left(-\frac{\mathbf{v}^2}{v_c^2}\right) & v < v_{\text{esc}} \\ 0 & v \ge v_{\text{esc}} \end{cases}$$

- Most probable DM speed: $v_c = 220 \text{ km/s}$
- Local DM velocity distribution:

$$f_{\text{gal}}(\mathbf{v}) = \begin{cases} N \exp\left(-\frac{\mathbf{v}^2}{v_c^2}\right) & v < v_{\text{esc}} \\ 0 & v \ge v_{\text{esc}} \end{cases}$$

How does the LMC change this picture?

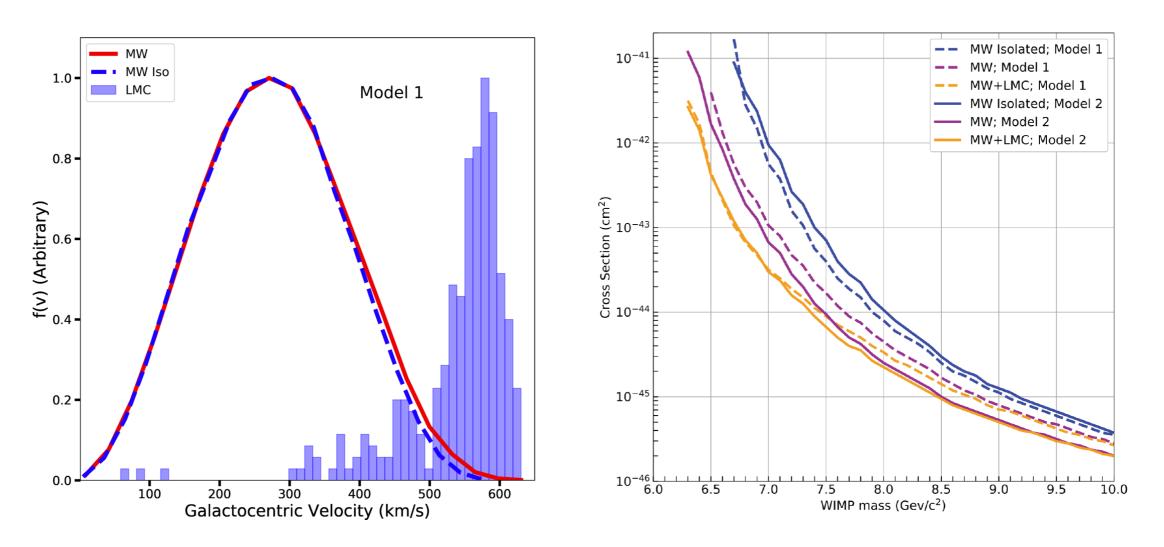

Effect of LMC on direct detection

- The LMC could perturb the high speed tail of the local DM velocity distribution. — Affects direct detection implications for low mass DM. Besla et al, JCAP 11, 013 (2019)
 - Donaldson et al, MNRAS 513, 1, 46 (2022)

Effect of LMC on direct detection

Fut.	Future MW-LMC analogue	0.175	80.3	

Matching the Sun-LMC geometry

 The LMC is predominately moving in the opposite direction of the Solar motion.
 Large relative speeds of DM particles originating from the LMC with respect to the sun.

Matching the Sun-LMC geometry

 The LMC is predominately moving in the opposite direction of the Solar motion.
 Large relative speeds of DM particles originating from the LMC with respect to the sun.

 Choose the position of the Sun in the simulations such that it matches the observed Sun-LMC geometry.

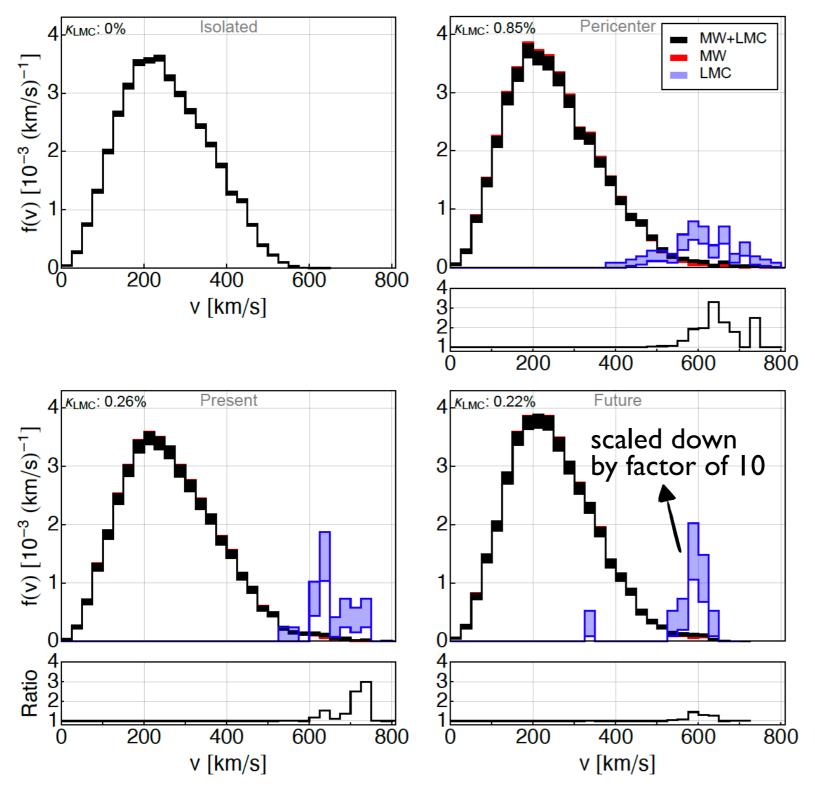

Local dark matter density

	Halo ID	$M_{\mathrm{Infall}}^{\mathrm{LMC}} \left[10^{11} \mathrm{M}_{\odot} \right]$	$ ho_{\chi} ~[{ m GeV/cm^3}]$	$\kappa_{\rm LMC}$ [%].	
·	1	0.31	0.21	0.14	Percentage of DM particles in
	2	0.31	0.23	0.64	the Solar region
	3	0.34	0.35	0.026	originating from the LMC
	4	0.82	0.34	0.096	
	5	1.84	0.24	1.5	
	6	1.10	0.38	0.038	
	7	0.32	0.53	0.032	
	8	0.36	0.38	0.0077	
	9	0.73	0.36	0.10	
	10	3.28	0.39	2.8	
	11	1.45	0.43	0.028	
	12	1.43	0.53	0.17	
	13	3.18	0.34	2.3	
	14	0.84	0.60	0.26	
	15	1.15	0.32	1.2	

 The percentage of DM particles in the Solar neighborhood originating from the LMC is small.

Local dark matter speed distribution

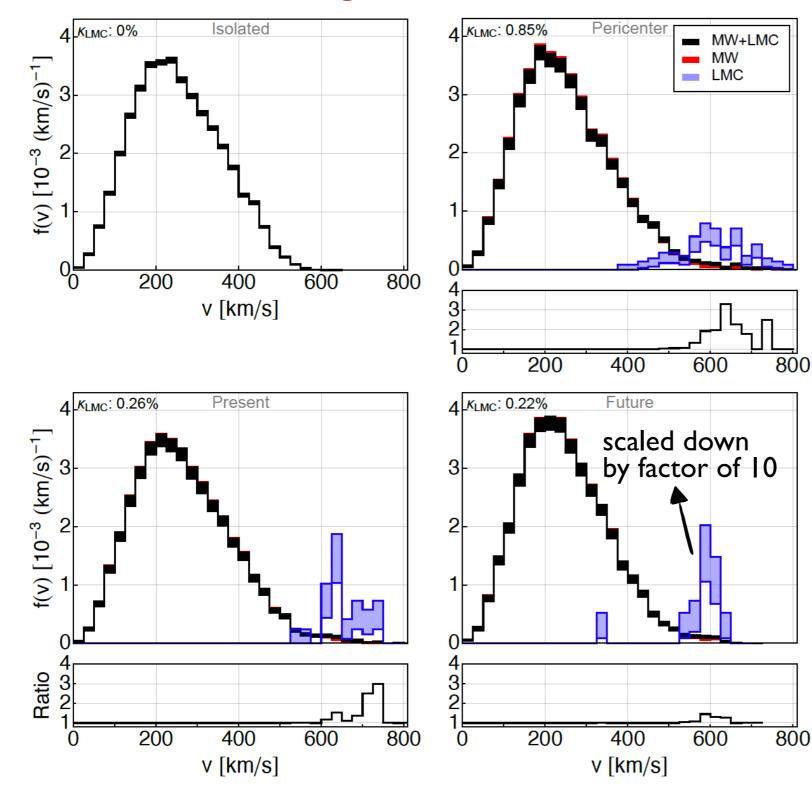

In the galactic rest frame

Smith-Orlik et al., JCAP 10, 070 (2023)

Local dark matter speed distribution

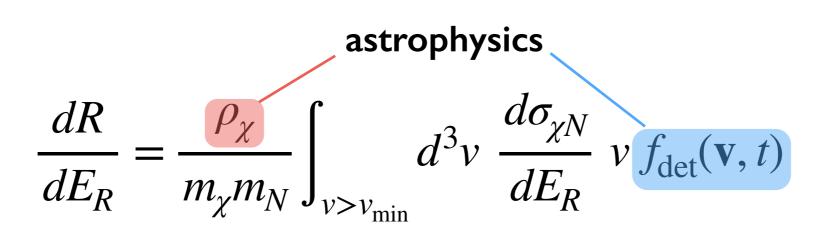

In the galactic rest frame

The LMC impacts the high speed tail of the DM speed distribution not only at its pericenter approach and the present day, but also up to ~175 Myr after the present day.

Direct detection event rate

• The differential event rate (per unit detector mass):

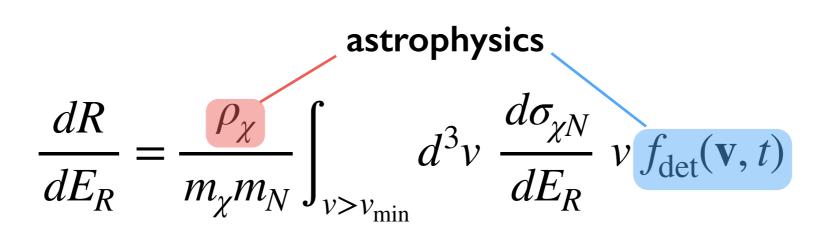

• For standard spin-independent and spin-dependent interactions:

$$\frac{dR}{dE_R} = \frac{\sigma_0 F^2(E_R)}{2m_\chi \mu_{\chi N}^2} \rho_\chi \eta(v_{\min}, t)$$

Direct detection event rate

• The differential event rate (per unit detector mass):

• For standard spin-independent and spin-dependent interactions:

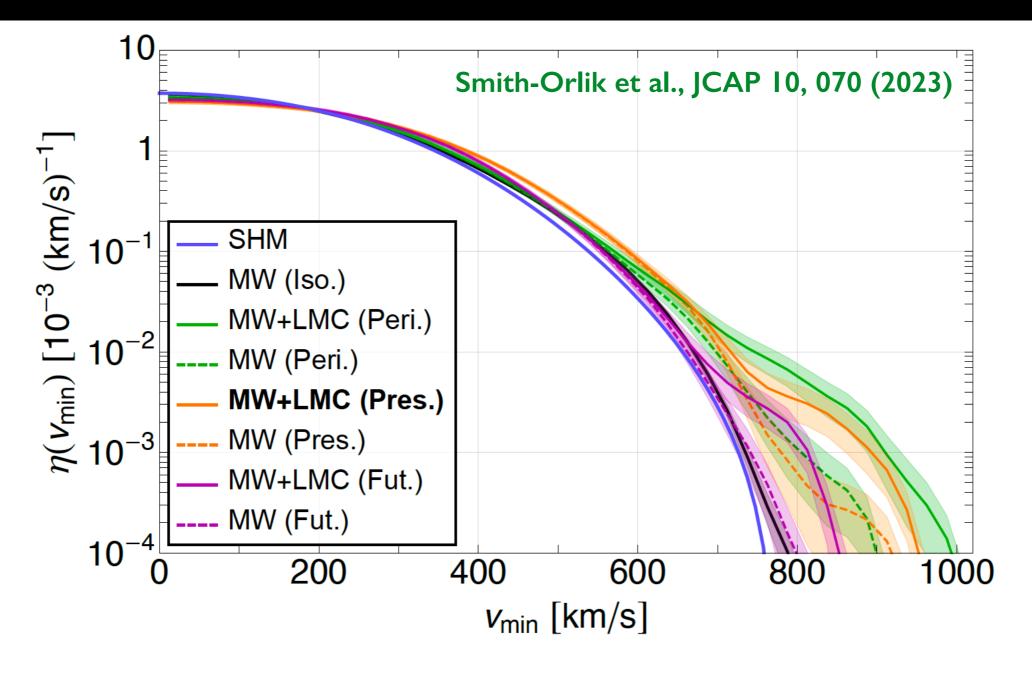

$$\frac{dR}{dE_R} = \frac{\sigma_0 F^2(E_R)}{2m_{\chi}\mu_{\chi N}^2} \frac{\text{astrophysics}}{\rho_{\chi} \eta(v_{\min}, t)}$$

where

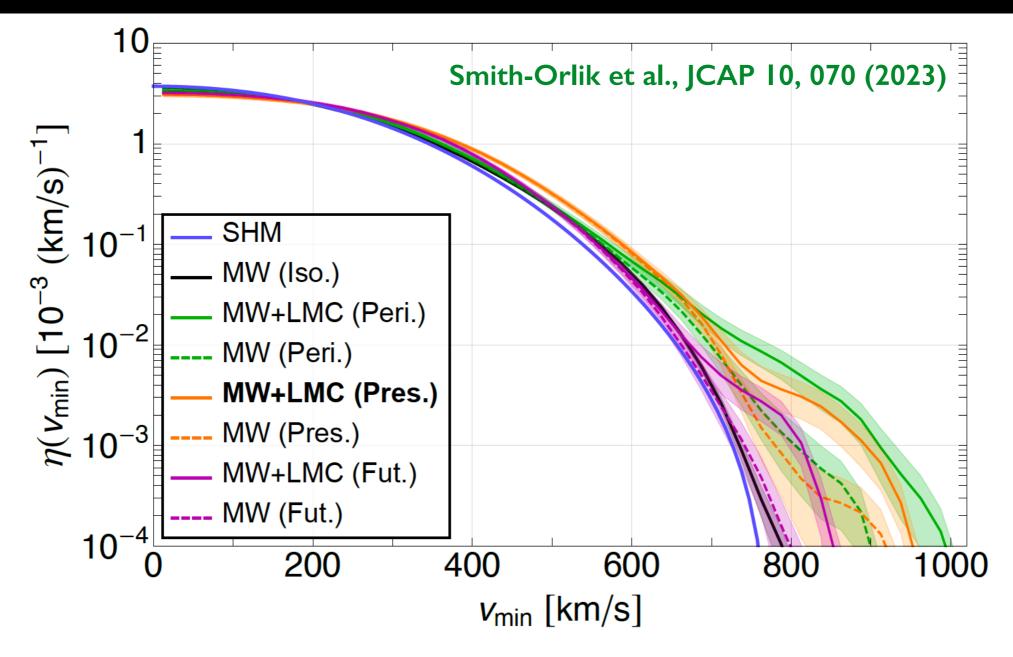

$$\eta(v_{\min}, t) \equiv \int_{v > v_{\min}} d^3 v \, \frac{f_{det}(\mathbf{v}, t)}{v}$$

Halo integral

Halo integrals

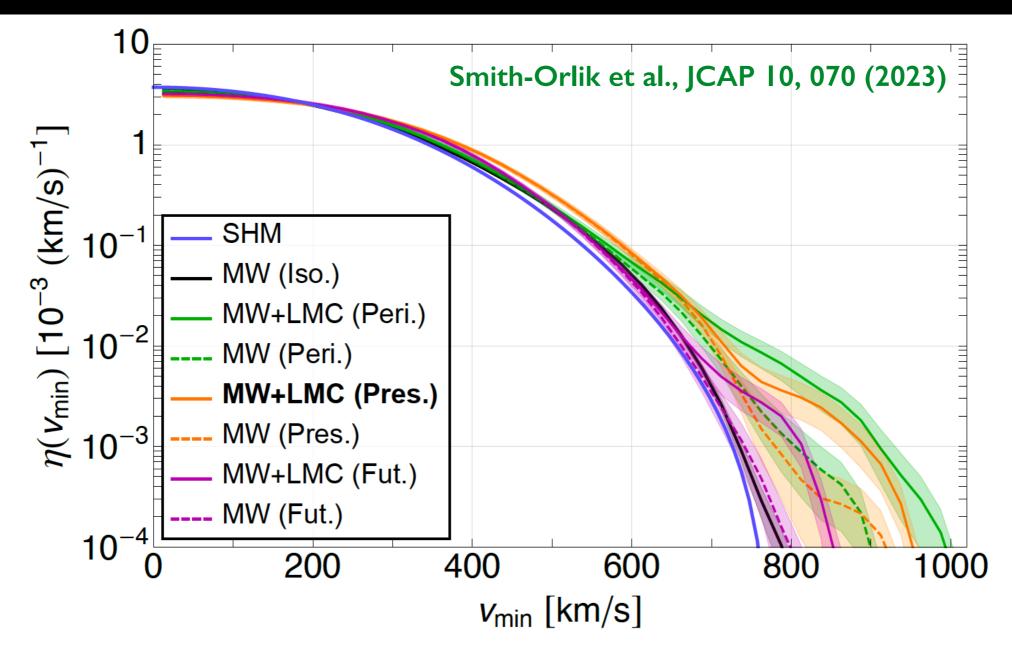

Halo integrals

 Two effects: High speed LMC particles in the Solar region + Milky Way's response to the LMC.

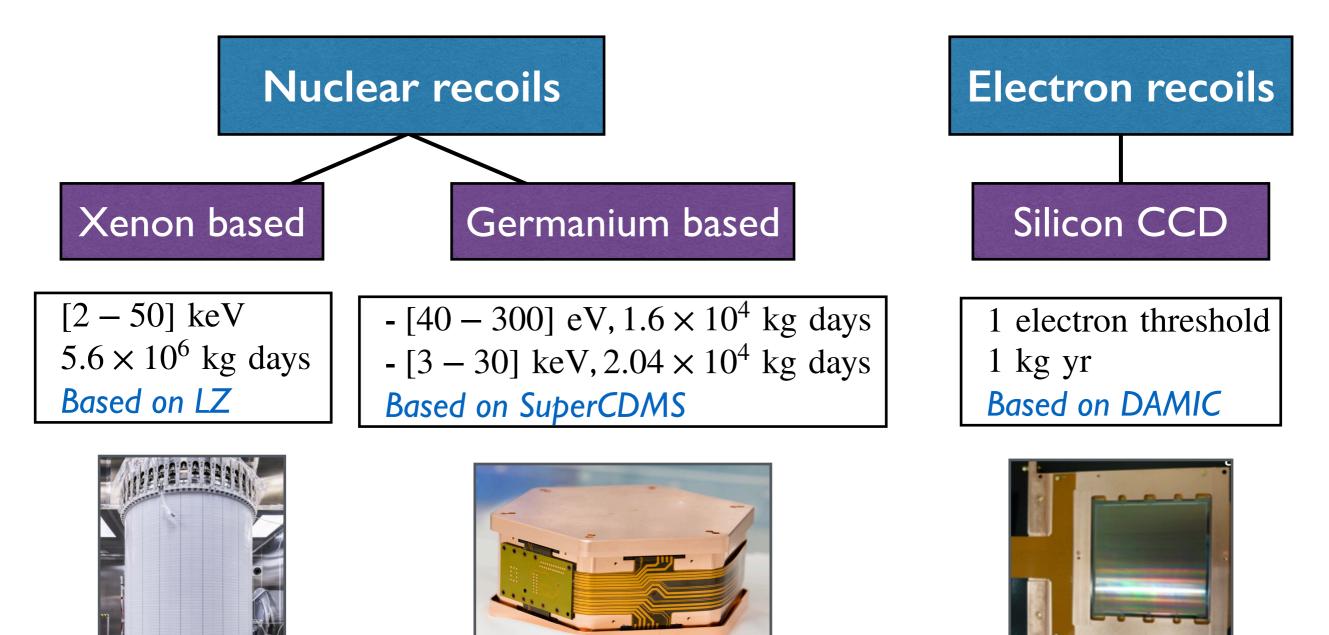

Halo integrals

Two effects: High speed LMC particles in the Solar region + Milky Way's response to the LMC.
 Shift of > 150 km/s in the high speed tail of the halo integrals at the present day.

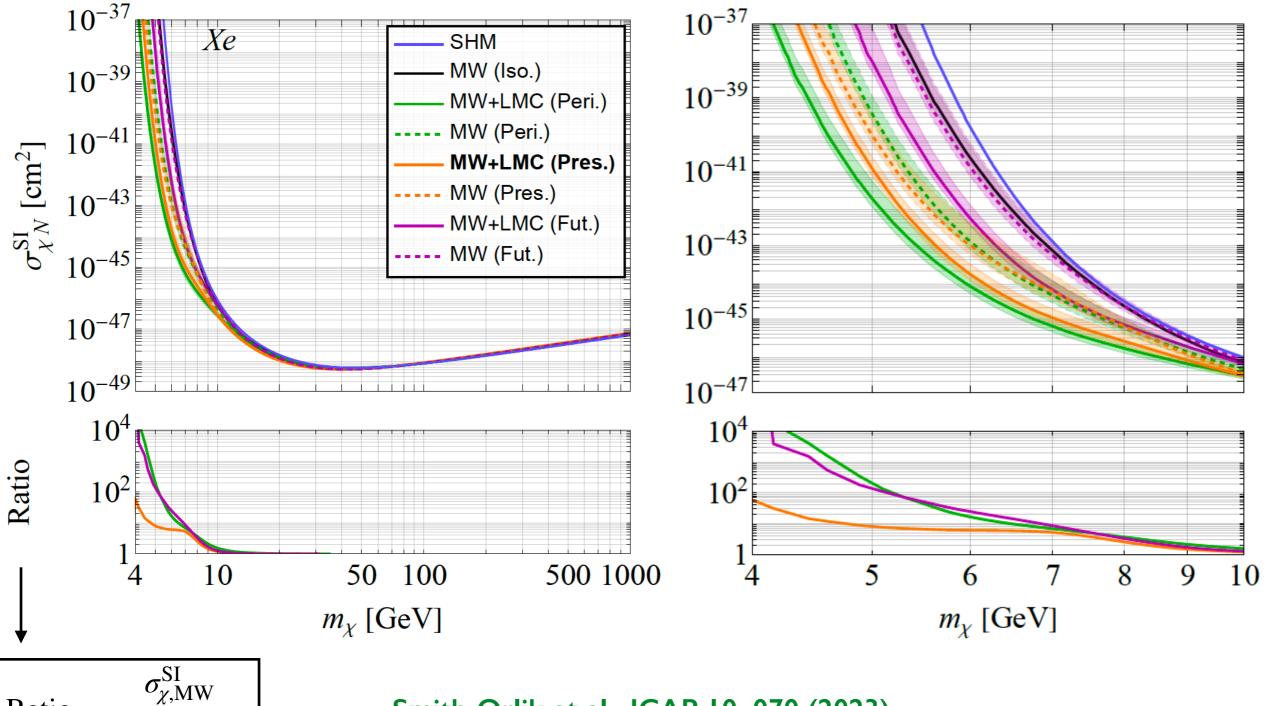

Direct detection exclusion limits

• Simulate the signals in 3 idealized near future direct detection experiments that would search for nuclear or electron recoils.

Xenon based detector:

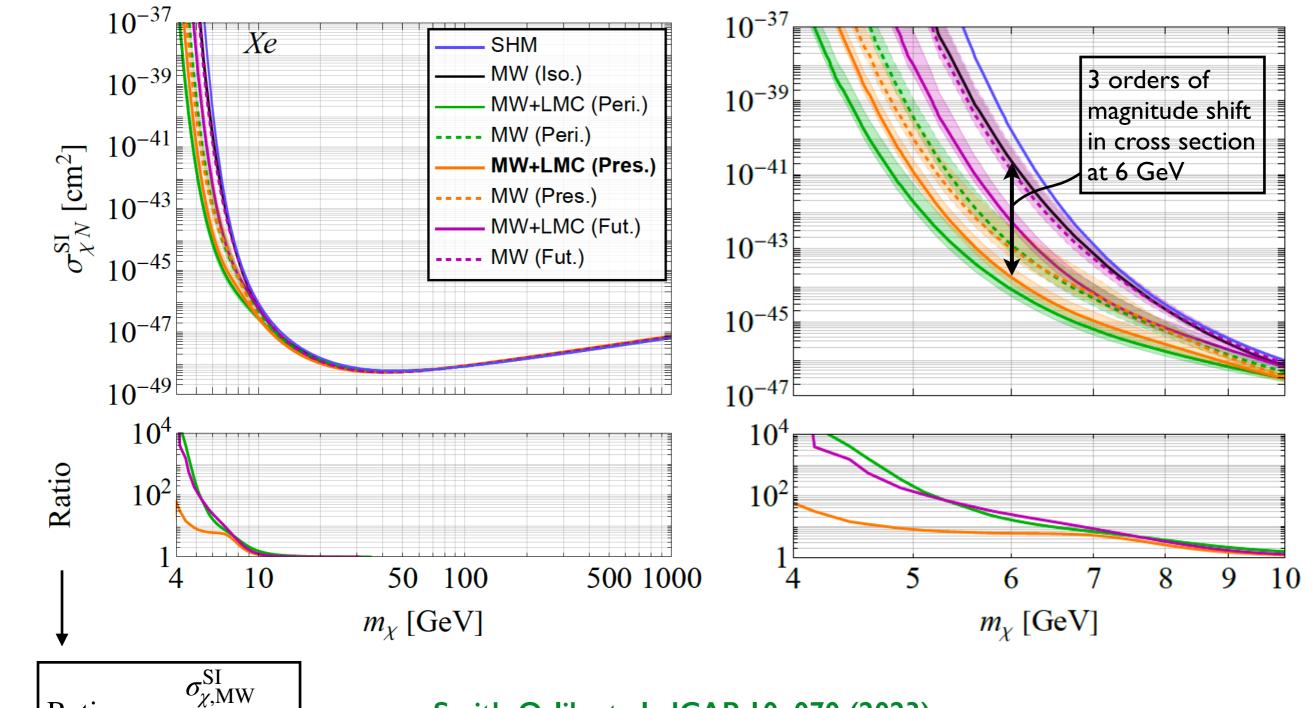

Fix $\rho_{\chi} = 0.3 \text{ GeV/cm}^3$

Ratio = $\frac{\sigma_{\chi,MW}}{\sigma_{\chi,MW+LMC}^{SI}}$

Xenon based detector:

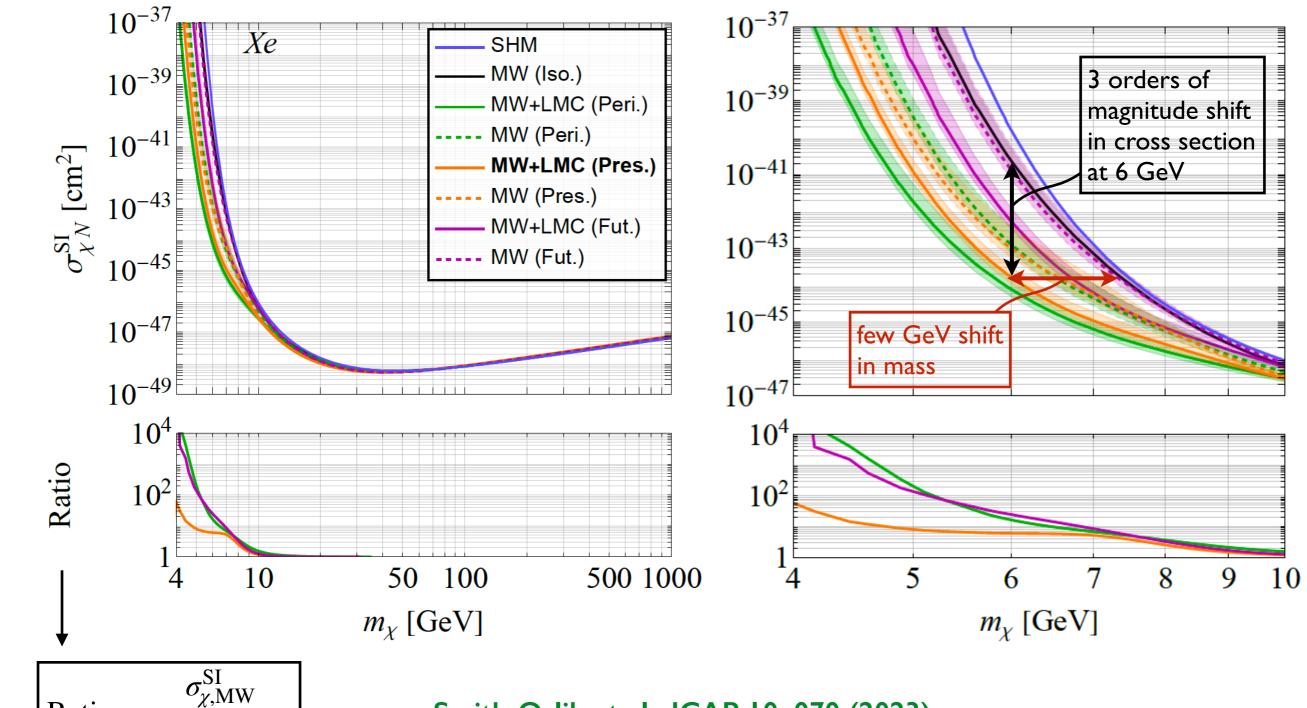

Fix $\rho_{\chi} = 0.3 \text{ GeV/cm}^3$

Ratio = $\frac{\sigma_{\chi,MW}}{\sigma_{\chi,MW+LMC}^{SI}}$

Xenon based detector:

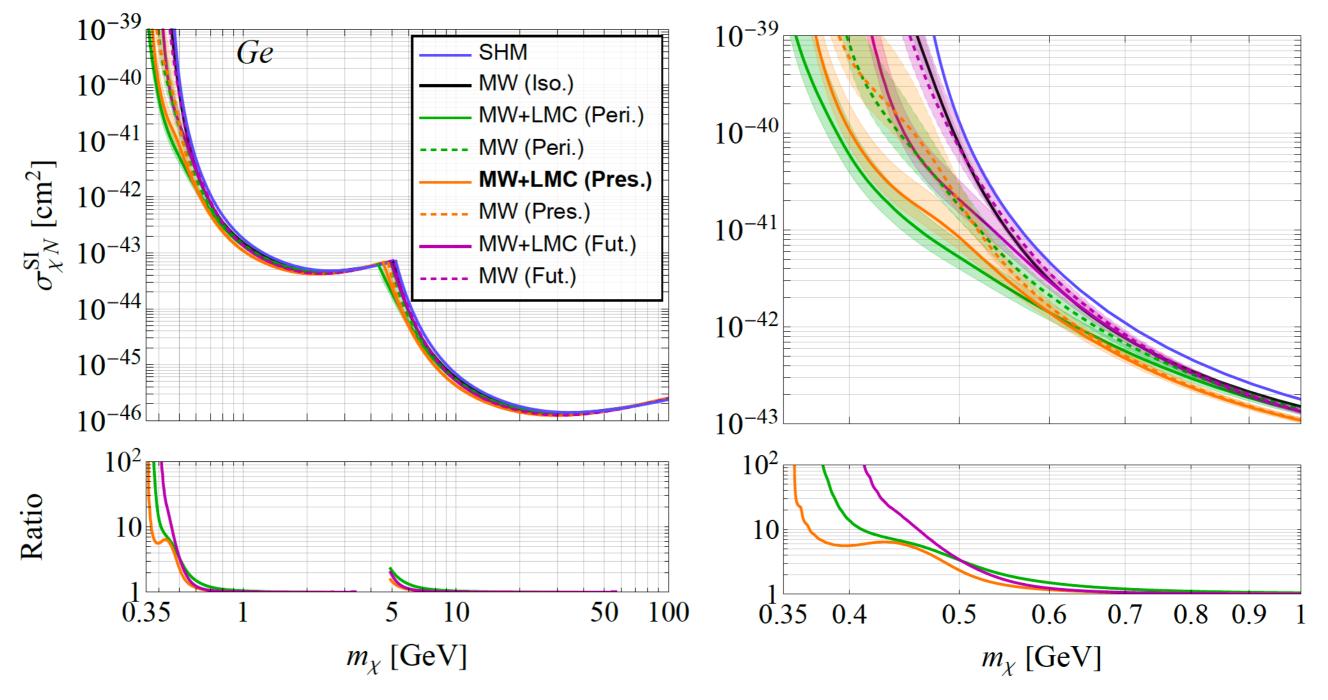

Fix $\rho_{\chi} = 0.3 \text{ GeV/cm}^3$

Ratio = $\frac{\sigma_{\chi,MW}}{\sigma_{\chi,MW+LMC}^{SI}}$

Germanium based detector:

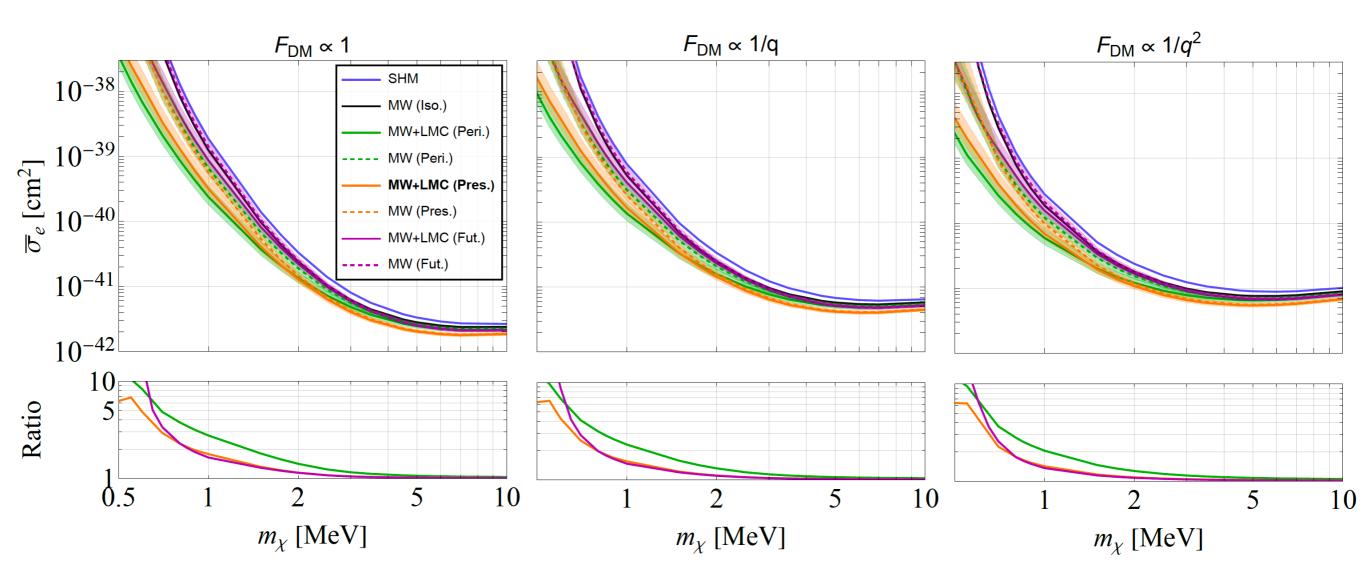

Smith-Orlik et al., JCAP 10, 070 (2023)

Direct detection: electron recoils

Silicon CCD detector:

Fix $\rho_{\chi} = 0.3 \text{ GeV/cm}^3$

Smith-Orlik et al., JCAP 10, 070 (2023)

• Parametrize possible DM-nucleon contact interactions using nonrelativistic effective field theory.

- Parametrize possible DM-nucleon contact interactions using nonrelativistic effective field theory.
- Consider an argon based detector (based on DarkSide-20k):

$$\mathcal{O}_{1} = 1_{\chi} 1_{N} \longrightarrow \mathbf{SI}$$

$$\mathcal{O}_{3} = i \, \vec{S}_{N} \cdot \left(\frac{\vec{q}}{m_{N}} \times \vec{v}_{\perp}\right)$$

$$\mathcal{O}_{5} = i \, \vec{S}_{\chi} \cdot \left(\frac{\vec{q}}{m_{N}} \times \vec{v}_{\perp}\right)$$

$$\mathcal{O}_{8} = \vec{S}_{\chi} \cdot \vec{v}_{\perp}$$

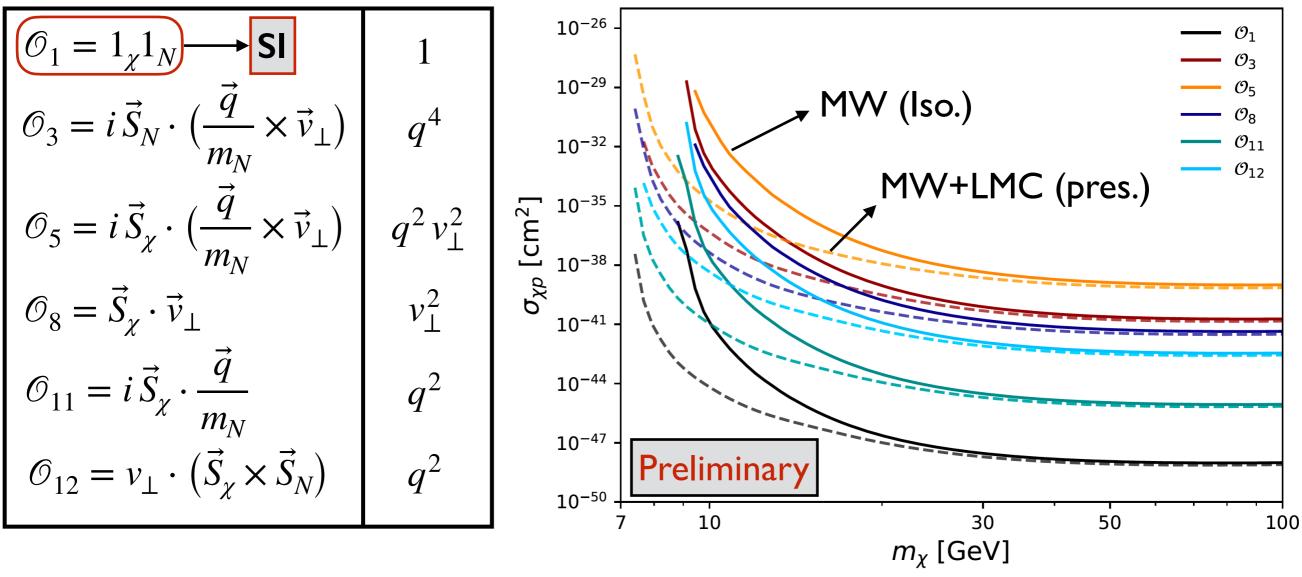

$$\mathcal{O}_{11} = i \, \vec{S}_{\chi} \cdot \frac{\vec{q}}{m_{N}}$$

$$\mathcal{O}_{12} = v_{\perp} \cdot \left(\vec{S}_{\chi} \times \vec{S}_{N}\right)$$

- Parametrize possible DM-nucleon contact interactions using nonrelativistic effective field theory.
- Consider an argon based detector (based on DarkSide-20k):

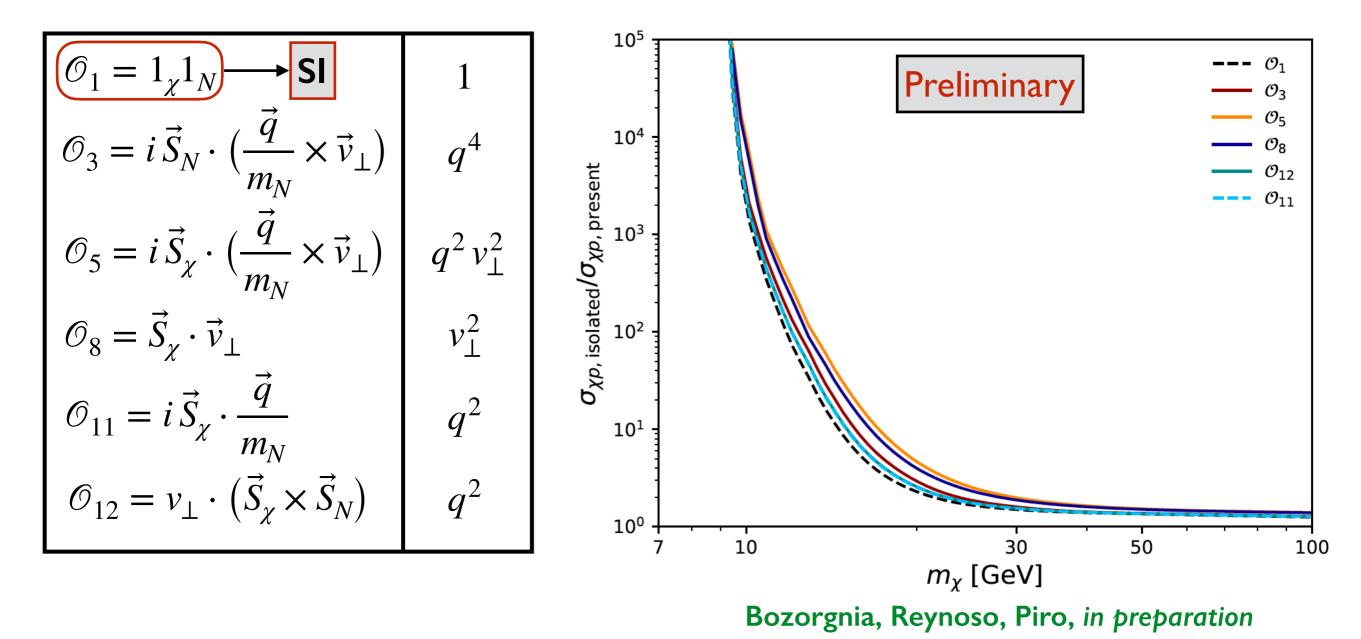

$$\begin{array}{l} \overbrace{\mathcal{O}_{1} = 1_{\chi} 1_{N}} \longrightarrow \mathbf{SI} & 1 \\ \overbrace{\mathcal{O}_{3} = i \, \vec{S}_{N} \cdot \left(\frac{\vec{q}}{m_{N}} \times \vec{v}_{\perp}\right)} & q^{4} \\ \overbrace{\mathcal{O}_{5} = i \, \vec{S}_{\chi} \cdot \left(\frac{\vec{q}}{m_{N}} \times \vec{v}_{\perp}\right)} & q^{2} v_{\perp}^{2} \\ \overbrace{\mathcal{O}_{8} = \vec{S}_{\chi} \cdot \vec{v}_{\perp}} & v_{\perp}^{2} \\ \overbrace{\mathcal{O}_{11} = i \, \vec{S}_{\chi} \cdot \frac{\vec{q}}{m_{N}}} & q^{2} \\ \overbrace{\mathcal{O}_{12} = v_{\perp} \cdot \left(\vec{S}_{\chi} \times \vec{S}_{N}\right)} & q^{2} \end{array}$$

- Parametrize possible DM-nucleon contact interactions using nonrelativistic effective field theory.
- Consider an argon based detector (based on DarkSide-20k):

Bozorgnia, Reynoso, Piro, in preparation

- Parametrize possible DM-nucleon contact interactions using nonrelativistic effective field theory.
- Consider an argon based detector (based on DarkSide-20k):

• LMC's influence on the local DM distribution is significant even in a fully cosmological simulation.

- LMC's influence on the local DM distribution is significant even in a fully cosmological simulation.
- Our particular Sun-LMC geometry maximizes the impact.

- LMC's influence on the local DM distribution is significant even in a fully cosmological simulation.
- Our particular Sun-LMC geometry maximizes the impact.
- Two effects boost the tail of the DM velocity distribution:
 - High speed DM particles from the LMC
 - Response of the Milky Way DM particles to the LMC

Significant shifts in direct detection limits

Significant shifts in direct detection limits

 LMC's impact even more significant for velocity-dependent effective operators. Backup Slides

Dark matter velocity distribution

Extract the DM distribution from cosmological simulations:

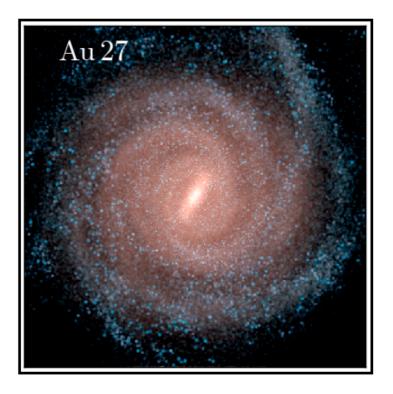

Rahimi, Vienneau, Bozorgnia, Robertson, 2023 (SIDM EAGLE)

Maxwellian distribution provides a good fit to the DM velocity distribution of Milky Way-like halos in cosmological simulations.

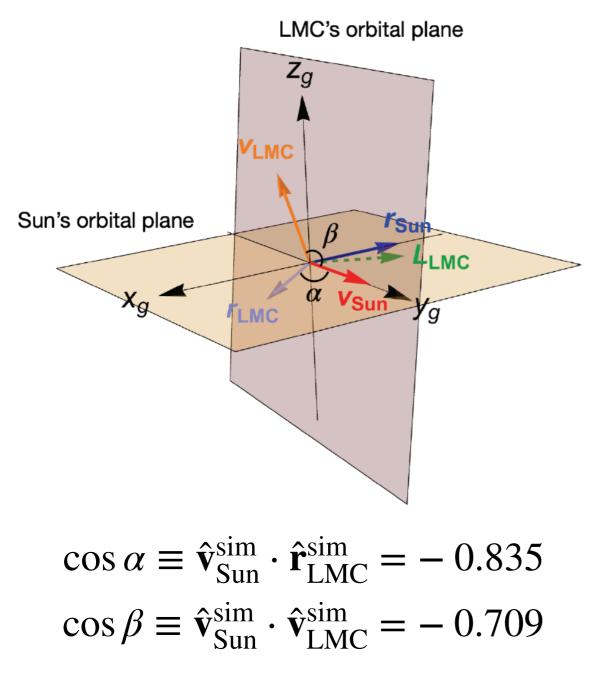

Identifying LMC analogues

- Select simulated LMC analogues that have properties similar to the observed LMC:
 - Present day stellar mass of the LMC: $\sim 2.7 \times 10^9 \ {\rm M}_{\odot}$
 - LMC's first pericenter distance: $\sim 48 \text{ kpc}$
- Difficult to find an exact LMC analogue in cosmological simulations. → Follow the history of the simulated halos within the last 8 Gyrs to find LMC analogues.
- Identify I5 LMC analogues based on two criteria:
 - LMC's stellar mass is $> 5 \times 10^8 M_{\odot}$.
 - **Distance from host** at first pericenter is in the range of [40,60] kpc.

Matching the Sun-LMC geometry

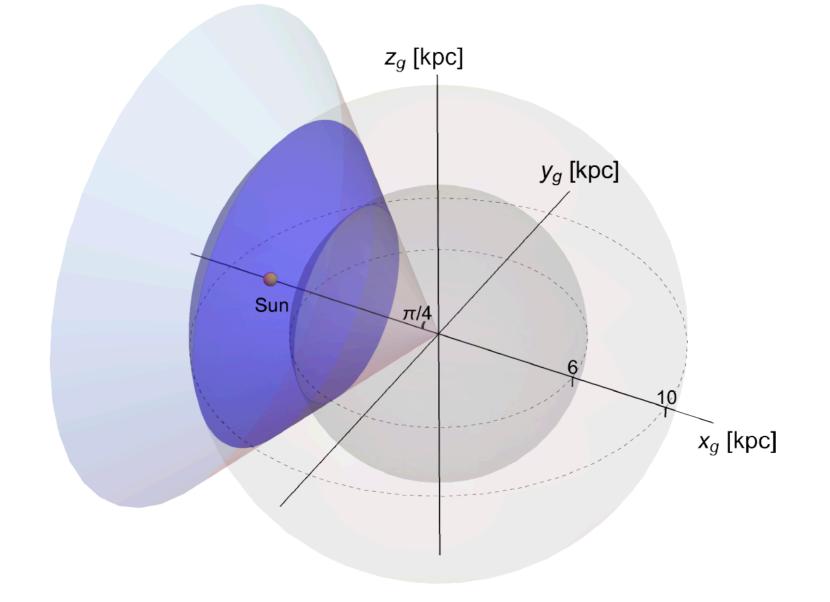

Steps in matching the Sun-LMC geometry to observations:

- I. Find the stellar disk orientations that make the same angle with the orbital plane of the LMC analogues as in observations.
- 2. Find the position of the Sun for each allowed disk by matching the angles between the angular momentum of the LMC and the Sun's position and velocity in the simulations to their observed values.
- 3. The best fit Sun's position is the one that leads to the closest match of the angles between the Sun's velocity and the LMC's position and velocity with observations.

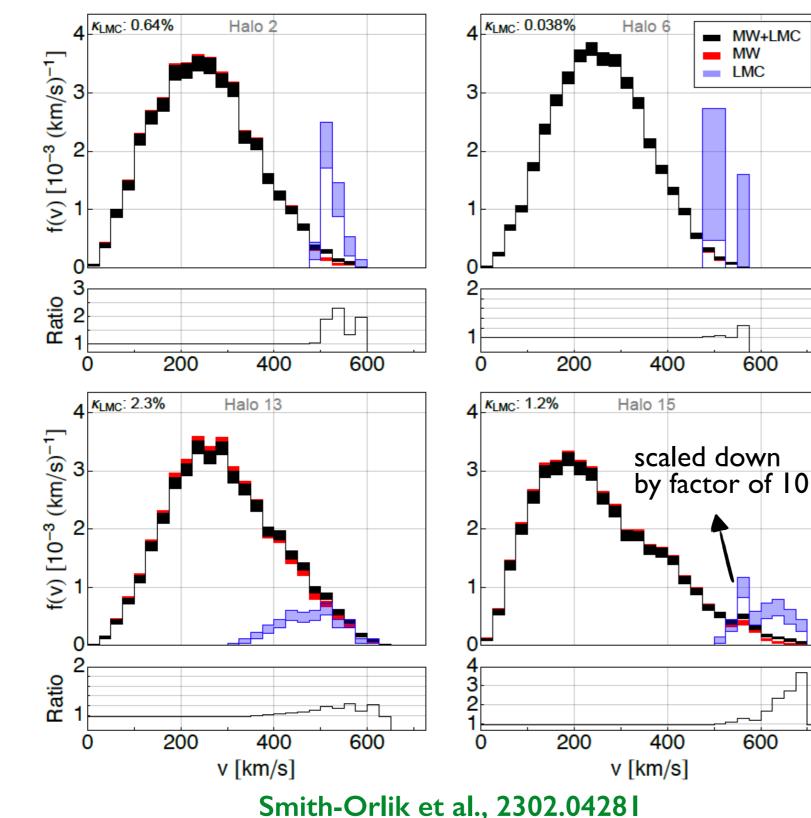

Defining the Solar region

Solar region: overlap of a spherical shell with radius between 6 - 10 kpc and a cone with opening angle $\pi/4$ with its axis aligned with the position of the Sun.

Local dark matter speed distribution

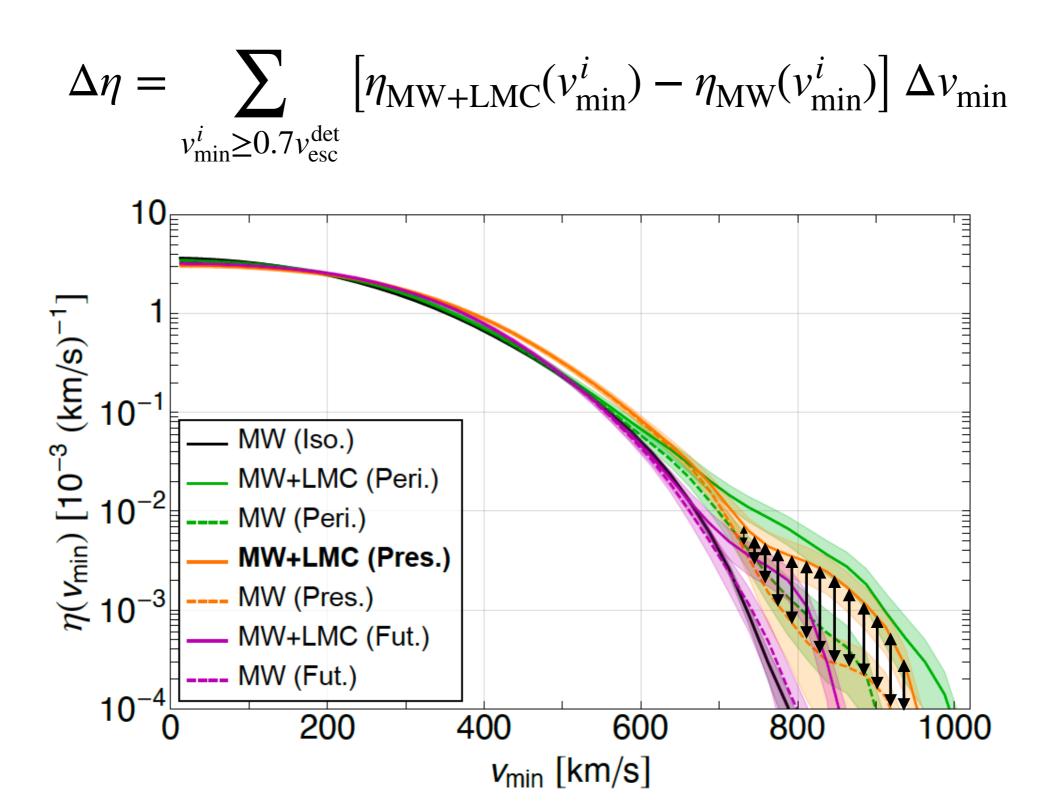

In the galactic rest frame (present day)

- The speed distribution of DM particles originating from the LMC peaks at the high speed tail of the Milky Way's DM distribution.
- Large halo-to-halo scatter in the results.

Changes in the halo integrals

Quantify the changes in the tails of the halo integrals by:

Changes in the halo integrals

Quantify the changes in the tails of the halo integrals by:

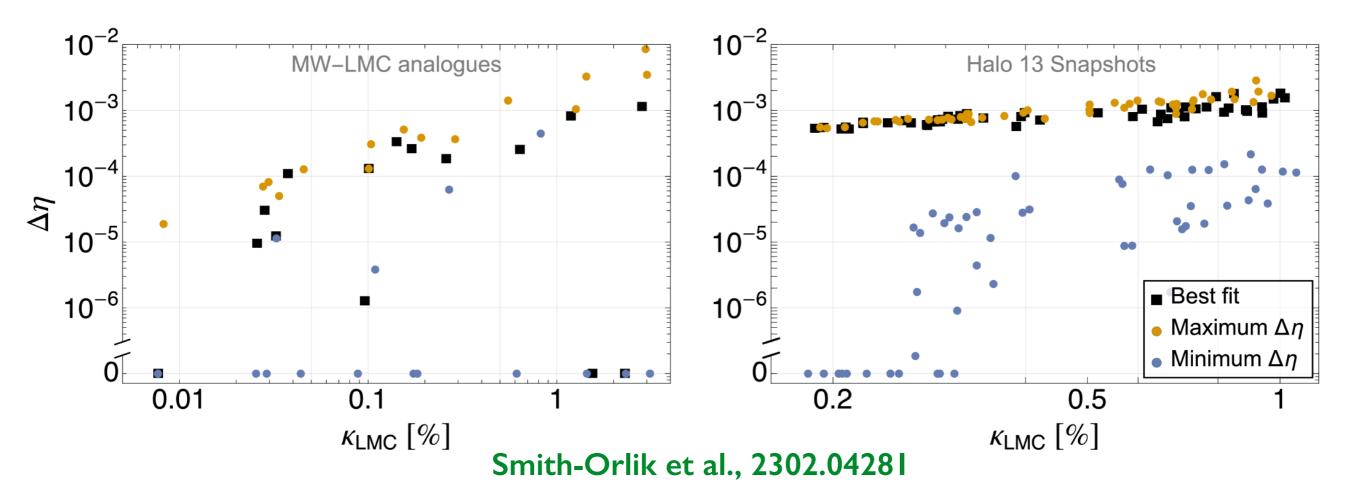

$$\Delta \eta = \sum_{\substack{v_{\min}^i \ge 0.7 v_{esc}^{det}}} \left[\eta_{\text{MW+LMC}}(v_{\min}^i) - \eta_{\text{MW}}(v_{\min}^i) \right] \Delta v_{\min}$$

Factors that contribute to changes in the tail of the halo integrals:

- I. Percentage of DM particles originating from the LMC in the Solar region.
- 2. The Sun's position in the simulations.
- 3. The Milky Way response due to the motion of the LMC.

Impact of the DM particles from the LMC

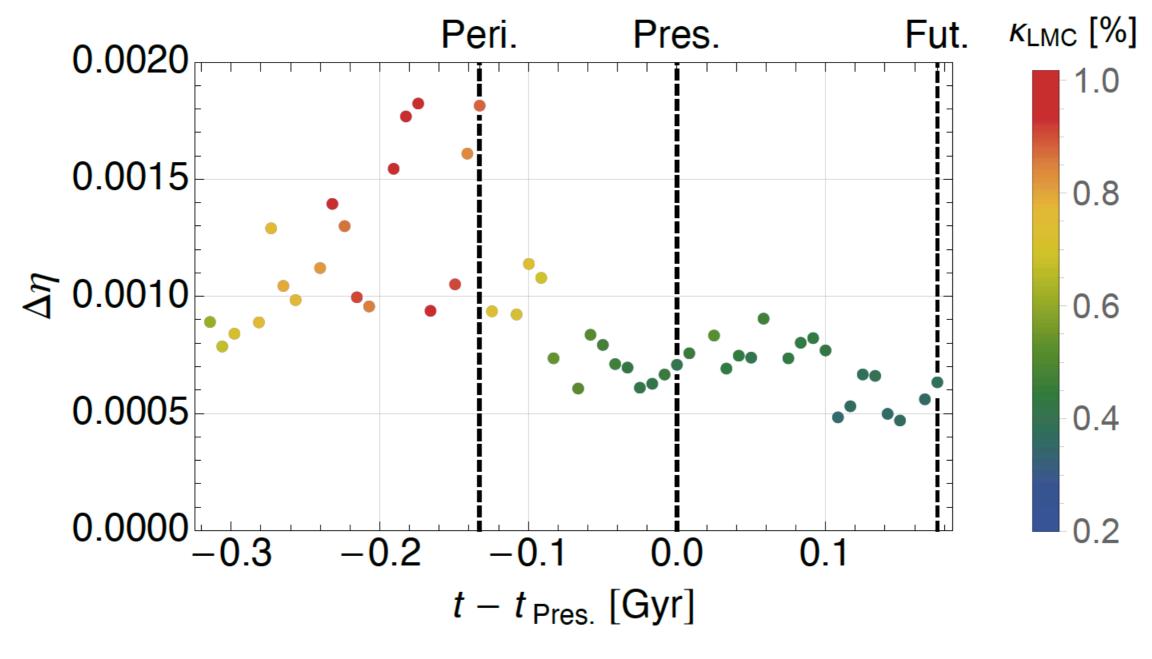

Correlations between the percentage of LMC DM particles in the Solar region (κ_{LMC}) and $\Delta \eta$:

- $\Delta \eta$ for best fit Sun's position close to max $\Delta \eta$, and increases with κ_{LMC} .
- Scatter in $\Delta \eta$ for halos with similar $\kappa_{\rm LMC}$, due to the choice of the Sun's position for specifying the Solar region.

Impact of the DM particles from the LMC

 $\Delta \eta$ for best fit Sun's position for different snapshots in one halo:

Smith-Orlik et al., 2302.04281

Variation with the Sun-LMC geometry

Smith-Orlik et al., 2302.04281

The best fit Sun's position is in a privileged position with respect to maximizing $\Delta \eta$. \rightarrow For the actual Milky Way, we expect the LMC to maximally affect the tail of the halo integral.
