

Search for a rare process:  
Higgs boson production with a single top quark  
Separation of  $tH$  and  $t\bar{t}H$   
Cut based vs. neural-network based selection

Finn von Ameln

Netzwerk Teilchenwelt - CERN Project weeks

03rd November 2023

- discovered in 2012
- short lifetime = “instant” decay
- only reconstructed by decay particles
- multiple decay channels, different branching ratios

for our dataset: 2 files,  $gg \rightarrow tHq$  /  $ttH \rightarrow yy$

gluon fusion main production mode

tHq, ttH rare

tHq not yet observed

fig. 1: The production modes of the Higgs boson

d = ttH, e,f = tHq

- The Higgs “gives” mass to fermions by Yukawa coupling
- mass  $t = 172.76$  (GeV)
- $tHq$  process,  $H$  can originate from  $t/W$
- interfering destructively in SM (hence a rare process)
- test Yukawa coupling in SM
- if Yukawa coupling different from SM = constructive?
  - then  $tHq$  more frequent

fig. 2: The Higgs production with a single top quarks

how can we see this process in a detector?

$t \rightarrow Wb$

$W \rightarrow \text{lepton}(\text{charged})\nu$  /  $W \rightarrow 2q$ ,

( $H \rightarrow yy$  in our dataset)

taking  $ttH$  = background

similar to  $tH$  but much more frequent

(+good background distinction with  $yy$ )

fig. 3: The Higgs production with a pair of top quarks

## CMS DETECTOR

Total weight : 14,000 tonnes  
 Overall diameter : 15.0 m  
 Overall length : 28.7 m  
 Magnetic field : 3.8 T

fig. 4: The CMS detector

- excellent invariant mass resolution
- small branching ratio (0.23%)

measurement (Run 2):

- we now see the signal and background
- fitting  $\rightarrow$  mass peak
- lower = fitting signal subtracting background
- tHq = clearer but less events

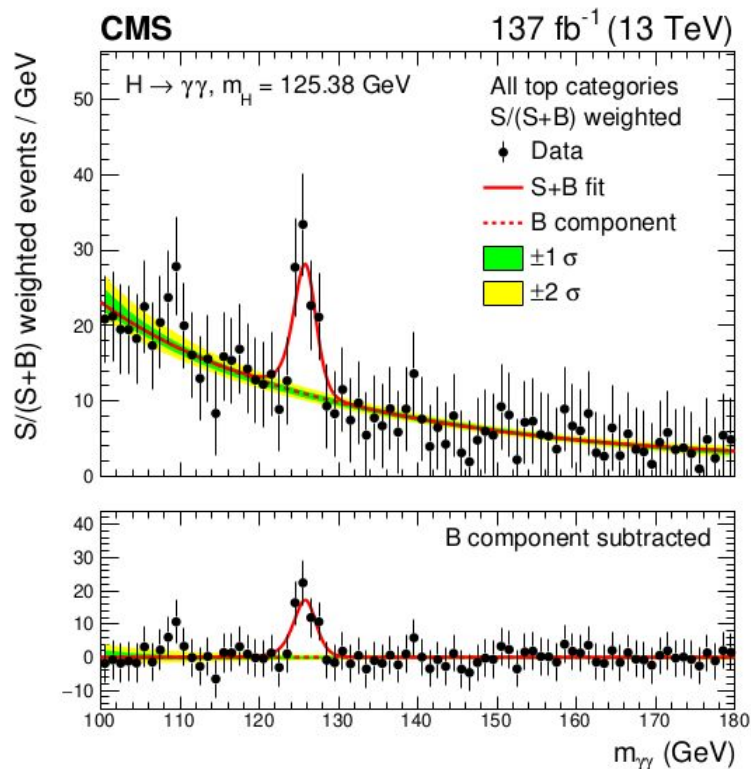

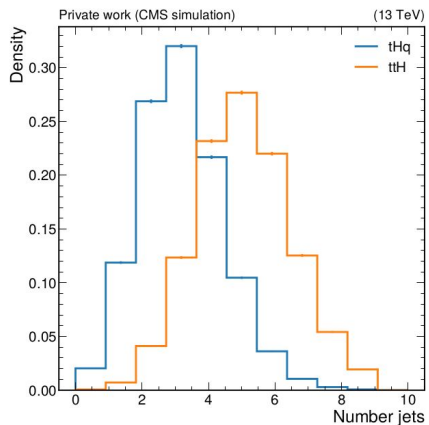

fig. 5: CMS invariant mass results for all top categories

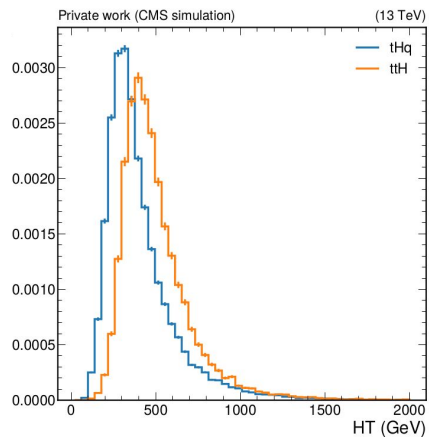

jet cut: number jets <5

[% remaining]

tHq: 85.87

ttH: 36.45

ht cut: ht <500 GeV

sum of all pt's

[% remaining]

tHq: 66.61

ttH: 22.15

lepton cut: number leptons <2

[% remaining]

tHq: 65.59

ttH: 20.74

btag cut: btag <1

sum 3 highest btag scores/event

[% remaining]

tHq: 44.03

ttH: 7.68

- information flows from input to output
- multiple layers of interconnected neurons
- each layer processing and transforming data to produce an output
- !optimizing by training
- Nodes = individual processing units
- Weights = adjustable parameters through training

fig. 6: Feed-forward-neural-network structure

events overall = 100.000

training data = 30.000

test data = 20.000

amount nodes = 20,20,10

batch size = 1024 beschreiben

epochs = 50 beschreiben

(binary classification problem:

loss = binary cross entropy

adam optimizer

activation = sigmoid, relu )

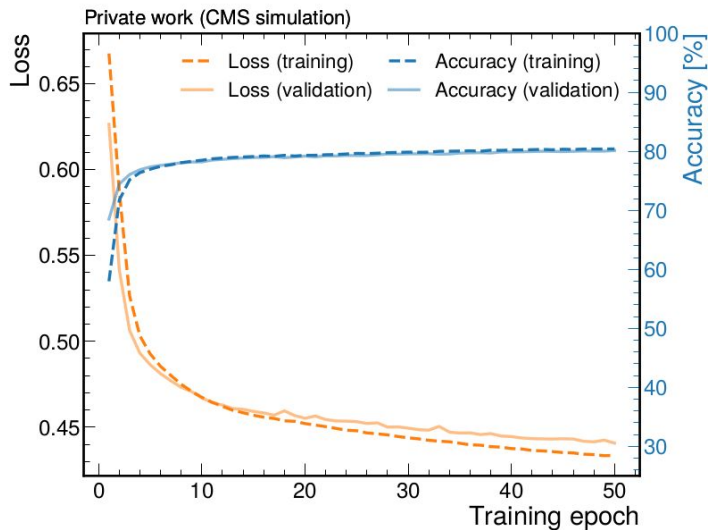

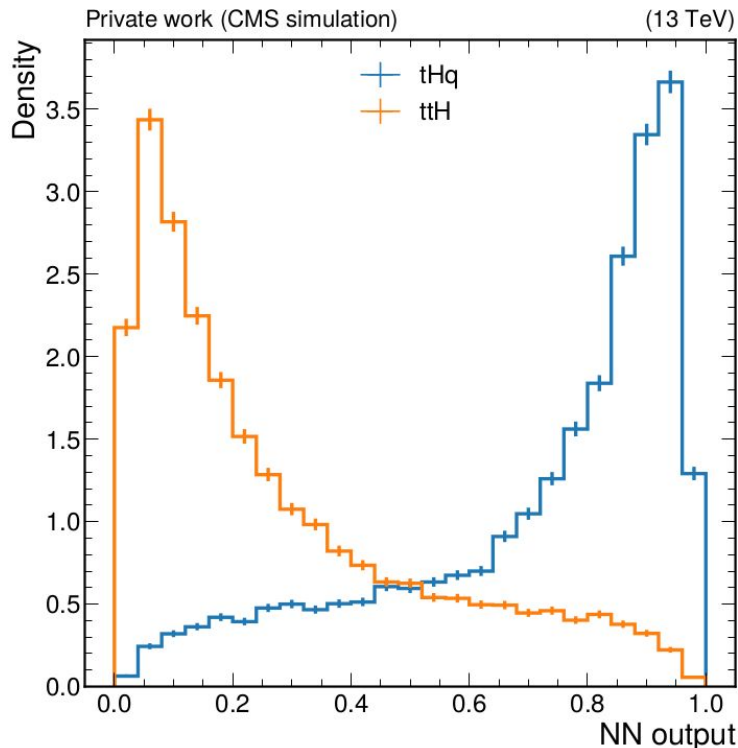

fig. 6: Feed-forward-neural-network structure

the nn can now separate ttH from tHq  
(functional approximation)

accuracy = events correctly classified

comparing cut based vs nn:

(different inputs!)

The nn's cuts are more efficient

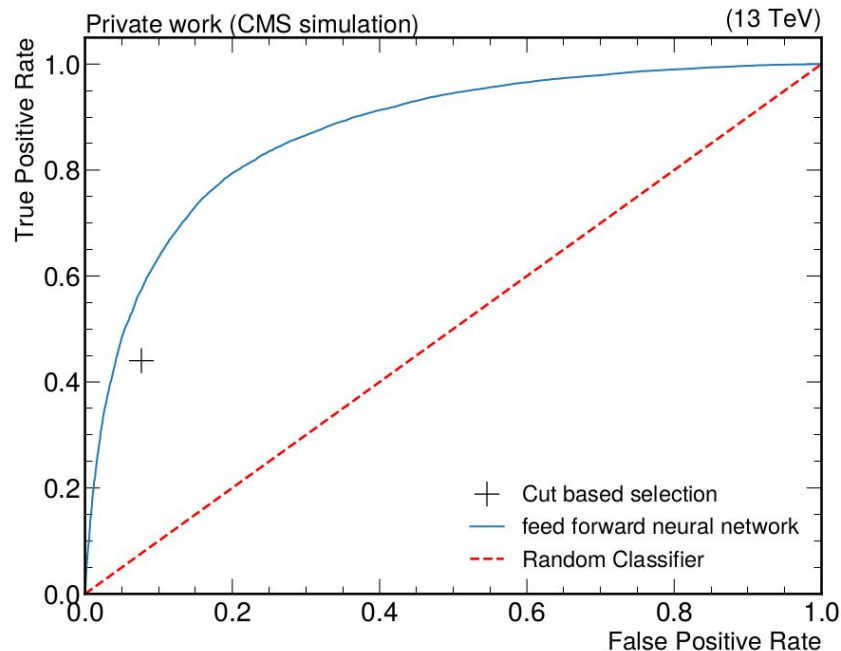

“higher” curve = better

there's still room for improvement:

- changing parameters

- adding more kinematic variables

- increasing amount events

Special thanks to Florian and Johannes,  
any feedback is welcome!

## CMS DETECTOR

Total weight : 14,000 tonnes  
Overall diameter : 15.0 m  
Overall length : 28.7 m  
Magnetic field : 3.8 T

- Current research: STXS-framework
  - Higgs production modes are defined base upon kinematic regions
  - allowing for easier separation
  
- Selecting kinematic variables to filter events
  - (some) STXS conditions implemented in python
  - (photon pre-selection already included)
  - azimuthal angle, pseudorapidity, ...
