

Session I - What is a quenched jet - Guilherme

Definition: *jet that has been modified through interaction with QGP*

- Modifications are seen in most observables (in distributions)
- An old problem: many jets within reconstructed p_T range are unmodified
- Can we tell, on a jet-by-jet basis, if a jet is quenched?
 - Quenched jets resemble in most unquenched jets
 - What information is needed to identify quenched jets? Can it be done?
- If a machine can learn, then information exists within reconstructed jets that allows for discrimination

Quenching or contamination ?

AA no medium response vs. pp
Decent discrimination

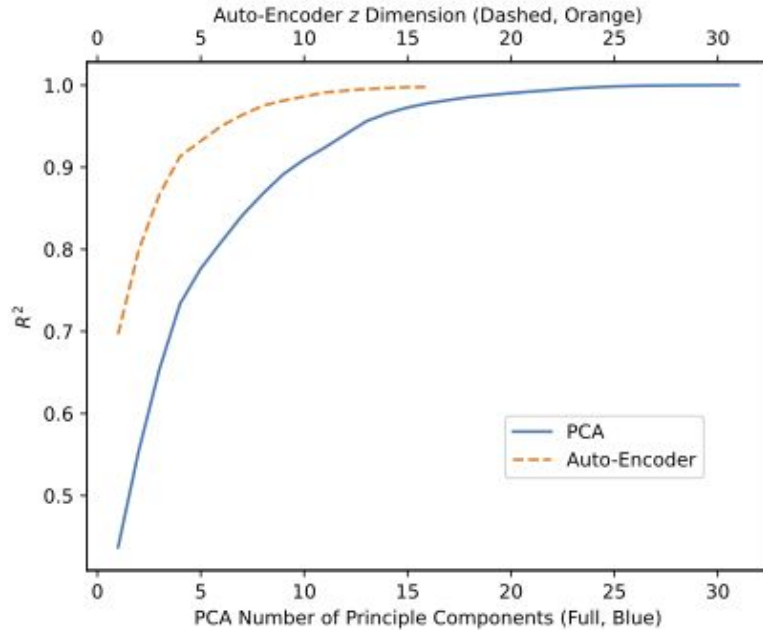

AA with medium response,
embedded and subtracted
Remarkable discrimination
[closest to exp?]

AA with medium response,
embedded and subtracted
pp embedded and subtracted
[true quenching]

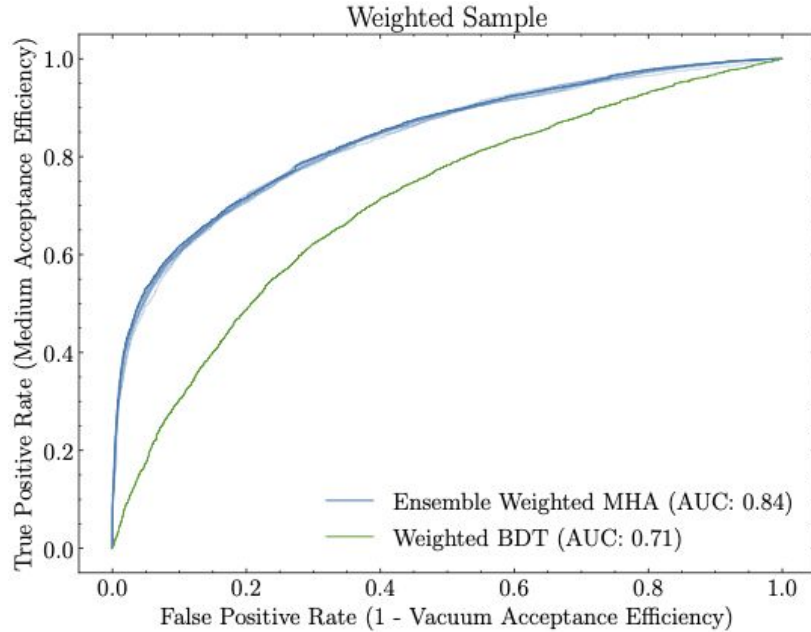

Based on large [~30] set of observables

Is more information better ?

- Information contained in observables is highly redundant [~ 5 independent quantities encode all info of ~ 30 observables]

Is more information better ?

- Discrimination from observables much lower than discrimination from jets as lists of 4-mom of constituents [full information]

Can we tell a quenched jet apart from an unquenched one ?

How ?
