Outline-Experiments

- ⊕ Collider/fixed target beams
- ⊕ Scintillation Counters
- ⊕ HPDs and Silicon Detectors
- ⊕ Wire Chambers
- ⊕ Cerenkov Counters
- ⊕ Discovery of Antiproton
- ⊕ Calorimeters
- ⊕ Water Cerenkov calorimeters: Super-Kamiokande, IceCube
- ⊕ Fixed target detector: NuTeV
- ⊕ LHC experiments CMS, LHCb

Overview

- ⊕ Many of the HEP experiments use a limited number of particle detectors repeatedly
 - ⊞ Scintillators
 - ⊞ Cerenkov counters
 - ⊞ Time-of-flight
 - ⊞ Calorimeters
 - ⊞ Wire tracking chambers
 - ⊞ Silicon tracking detectors
- ⊕ Goal of particle detectors is to determine properties of particles, P , V , M , charge, ...
- ⊕ Important to be familiar with these. (Can help with physics analyses, ...)

Detector Subsystems

Particle type	Tracking	ECAL	HCAL	Muon

CERN LHC

LHC Hadron Collider beam properties

- ⊕ Proton-proton LHC center of mass energy 14 TeV. $E_{cm} = 2 E_{beam}$
- ⊕ $10^{34} \text{ cm}^2\text{sec}^{-1}$ luminosity
- ⊕ Collision region length sigma $\sim 5\text{cm}$
- ⊕ Interaction region cross section $100\mu\text{m}$
- ⊕ Event rate $> 100,000,000$ per second
- ⊕ Good stability of collision point
- ⊕ Collision period 25 ns between crossings
- ⊕ High Radiation fields, especially at forward angles

Fixed target experiment

- ✚ Beam energy up to 400 GeV
- ✚ beam structure (18 ns bunches at FNAL)
- ✚ flat top, up to 10^{13} particles over 2 second spill
- ✚ $E_{cm} = (2m_{\text{target}}E_{\text{beam}})^{1/2}$
- ✚ event rate determined by particles per spill. Can be extremely large.
- ✚ radiation fields can be extremely large at target region.
- ✚ Target can be gas jet, liquids, metals, active instrumented targets.

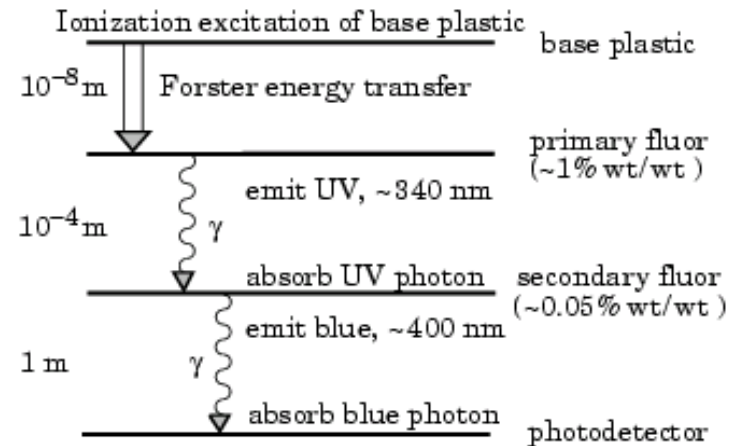

Simplest Detector? Scintillation Counters

Organic Scintillator

Scintillator plastic very commonly used in HEP. Light production mechanism complicated. To make scintillator, start with scintillator base material, plastic containing benzene rings (polystyrene). The base material is sensitive to ionization energy loss of the particle. Molecules of the base material are excited into vibrational modes. Add Primary Fluor, a chemical that is excited by the vibrational mode of the base molecule and emits UV photon.) (Forster mechanism). Then add secondary fluor that absorbs UV photon, re-emits at a longer wavelength (called Stokes Shift of fluor). The UV photon is typically absorbed and shifted within 1mm of it's creation. The Stokes shift is necessary to prevent re-absorption of the UV photon by the primary fluor, hence improving attenuation length of the light in the material..

Light Guides and Liouville's Theorem

Liouville's Theorem is that the density of points in phase space is an incompressible fluid. For instance if you squeeze the x variable, you expand the p variable.

Photons in a light guide can be treated as points in phase space, with the variables: the transverse coordinate in the light guide; and the photon's angle.

Compressing the transverse coordinates too much will cause the photon angle to increase beyond the critical angle for total internal reflection, and the photon will escape from the light guide. Designing good light guides is subtle.

Use of wave-length shifting a way around Liouville's Theorem.

The PMT is often coupled to the scintillator through a light guide

Wavelength shifting

Light emitted by scintillator is absorbed and re-emitted by wavelength shifter in a light guide. The new photon is emitted isotropically. Depending on the design of the light guide, 10-30% of the light can be captured in the light guide and carried to the photo-detector. In this way a very large compression of the density of light can be achieved. The ratio of the cross section of the scintillator to the cross section of the light guide can be quite large.

→ cost savings in photocathode area. (CMS HCAL has $\sim 800 \text{ cm}^2$ of photocathode)

→ Reduce cracks

→ Example Tile/Fiber

Optical fiber doped with wavelength shifter acts as light guide. Fiber is placed in a groove in the scintillator, absorbs scintillator light, re-emits it. About 5% of the light is captured in the fiber

IF, Primorsko, June 2012

Wavelength Shifters

Another example of wavelength shifting to concentrate light.
Calorimeter

Photomultiplier

Uses photoelectric effect to convert photon to electron, then electron multiplication. Invented in 1930. Still heavily used.

Photomultipliers

Photomultiplier

Properties:

- Window
- Photocathode
- Quantum Efficiency
- Single pe resolution
- Gain
- Speed
- Noise

Resistor-divider pmt base

PMT – Photocathodes and windows

Figure 3-3: Spectral transmittance of window materials

Transmission for types of phototube window

Quantum Efficiency for various types of photocathode material

Photomultiplier – secondary emission

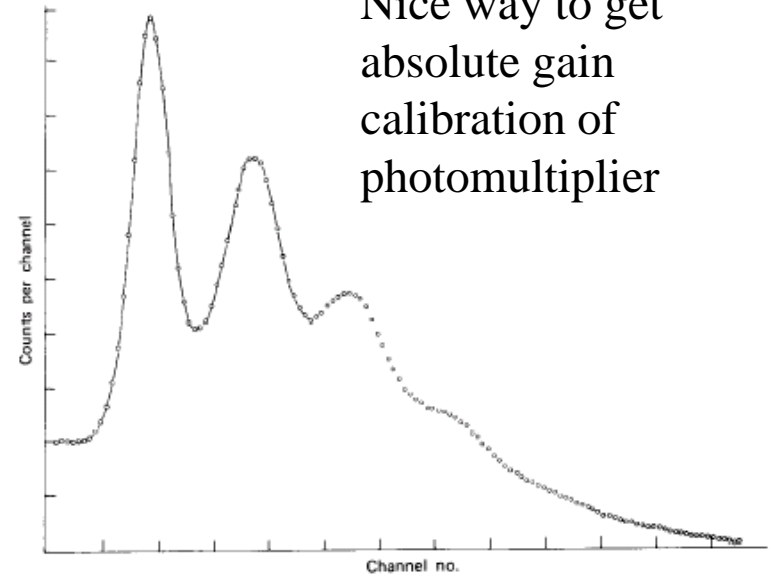

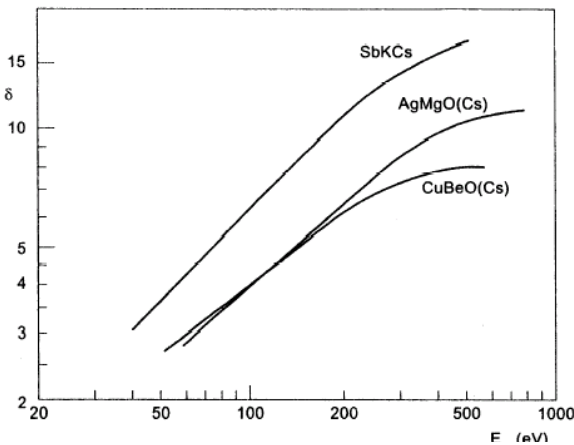

$$\delta = 5$$

High emission dynodes allow resolution of single photoelectrons

$$\delta = 25$$

Secondary emission coefficients of commonly used dynode materials vs. incident electron energy:

Nice way to get absolute gain calibration of photomultiplier

Specialty PMTs

Solar blind small metal package PMT

The R9875U is a small metal package PMT, whose Cs-Te photocathode features excellent solar blind characteristics. This new tube offers high sensitivity in the VUV region, whilst also having a high resistance to shock and vibration. This makes the R9875U ideal for more demanding applications.

Features

- Excellent solar blind characteristics
- High shock and vibration resistance
- High VUV sensitivity
- Small form factor

Applications

- Fire detection
- UV-LIDAR

Specifications

- Spectral range 160 nm to 320 nm
- Low dark current of 10 pA
- High gain of 3.7×10^5

Author: Richard Harvey, Hamamatsu Photonics UK

8 x 8 multianode PMTs featuring super bialkali photocathode technology

Hamamatsu Photonics are pleased to introduce the latest product in their successful multianode PMT range. The H10966A-100 and H10966B-100 have a high effective area ratio allowing them to cover a wide area by placing multiple detectors side by side. Coupled with their high quantum efficiency of 35% at 420 nm these detectors are ideal for large area scintillation work.

For ease the H10966A-100 comes with high voltage cable assembly attached for integration into systems.

Features

- High QE – up to 35% at peak
- 64 pixels
- Small dead space
- Fast time response

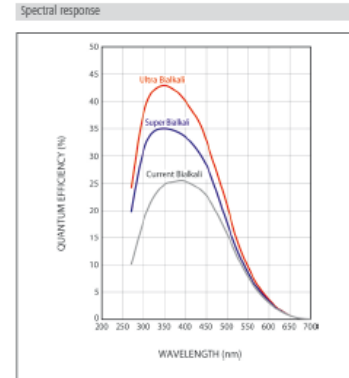

Applications

- High resolution PET
- Gamma camera
- 2-D radiation monitor

Specifications

- 8 x 8 multianode PMT
- 52 mm square
- Spectral range of 300 to 650 nm
- Gain of 3.2×10^6

Author: Robin Smith, Hamamatsu Photonics UK

+/- of PMTs

Fig.4.36 Relative gain variation as a function of magnetic field: (a) for a tube with linear focusing dynodes, (b) for a tube with venetian-blind dynodes.
curve 1: field aligned with y-axis (Fig.4.35)
curve 2: field aligned with x-axis
curve 3: field aligned with z-axis

Severe magnetic field gain dependence

Positives

- Large photocathode area possible
- Radiation Hard
- Small temperature dependence
- High Gain (1E5 – 1E7)

Negatives

- High Voltage 1K +
- Large volume
- Magnetic field sensitivity
- Expense (up to \$1K per channel)

CDF Time of Flight Counters

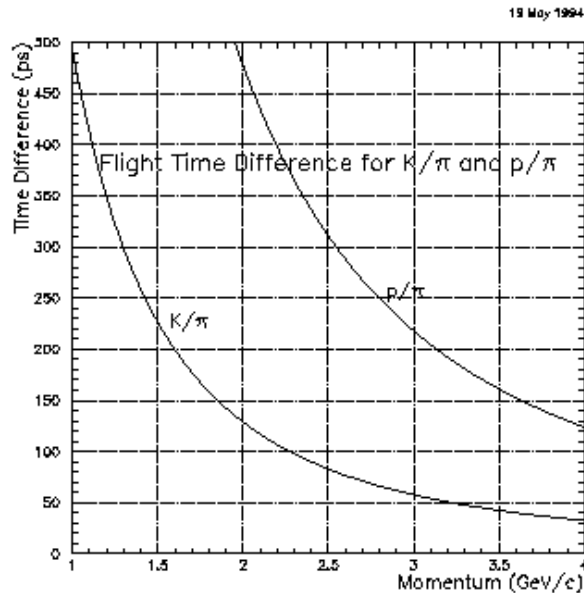

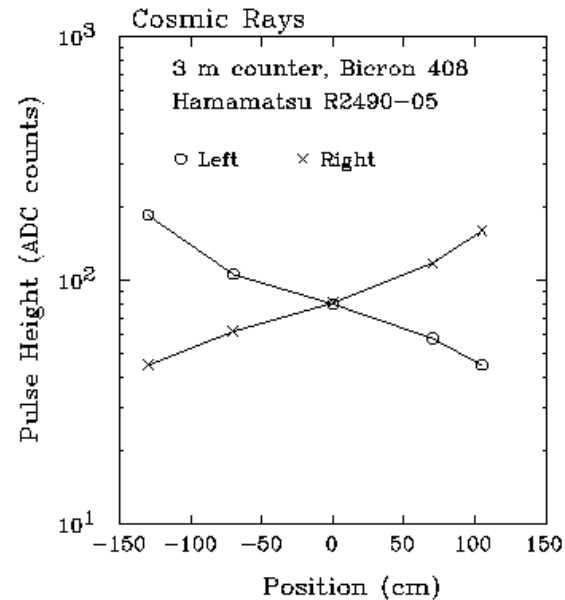

Figure 1: Flight time difference at a radius of 1.4 m (CDF location) versus momentum for π/K and π/p .

Cosmic ray test. Pulse ht vs position

Discriminators and Time Walk

Leading Edge Timing

Phototube pulse showing amplitude variation (position, ...)

Differentiated signal shows very little shift of zero-crossing time vs amplitude

→ zero-crossing discriminator

Scintillation Counter Problem

Some typical parameters for a plastic scintillation counter are:

energy loss in plastic scintillator:	2MeV/cm
scintillation efficiency of plastic:	1 photon/100 eV
collection efficiency (# photons reaching PMT):	0.1
quantum efficiency of PMT	0.25
gain of phototube	10**6
Pulse length	50 ns

What electrical signal do we get (into 50 ohms) for minimum ionizing particle going through 1 cm thick scintillator counter?

Poisson probability to get n for mean $\langle n \rangle$ is

$$P(n) = \frac{\langle n \rangle^n e^{-\langle n \rangle}}{n!}$$

What is probability our counter got zero photoelectrons?

Silicon Track Detector (CMS tracker)

Reverse-biased pn diode.
Gain=1, signal $\sim 1000e$
Strip pitch ~ 100 microns
Strips 10 – 20 cm long

CMS - All Si tracking

Pixel detector – Same operation as strips

- ▶ bump-bonded sensor/readout chip sandwich

- ▶ 100x150 μm pixels

CMS ~ 60M channels

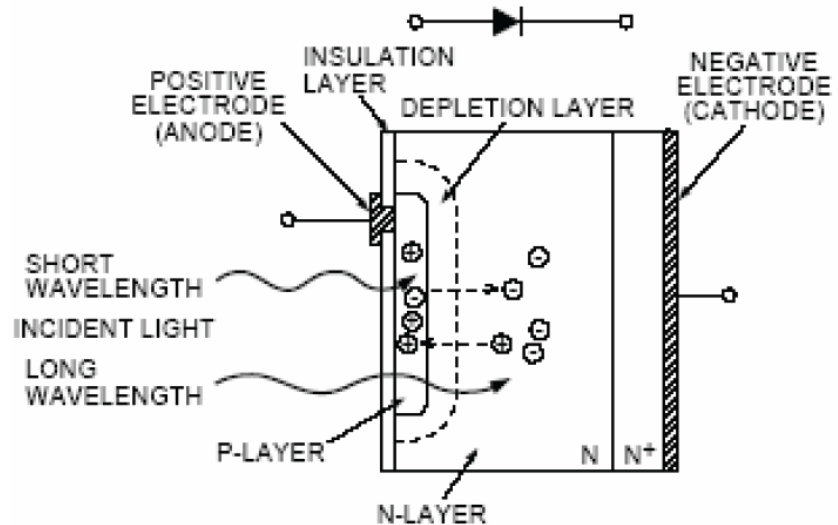

Photodiode: PN junction reverse biased

Photodiode

QE up to 80% +
Gain = 1

Solid State Photodetector: APD

Avalanche photodiodes are photodiodes with built-in high electric field region. With increasing reverse bias voltage, electrons (or holes) are accelerated and can create additional electron-hole pairs through impact ionization \rightarrow gain.

Two $5 \times 5 \text{ mm}^2$ APD's/crystal.
Gain – 50.
QE – 80% @ 420 nm.
Temp sensitivity – $-2.4\%/^{\circ}\text{C}$.

Note: If you reverse bias high enough voltage, avalanche causes geiger breakdown

Silicon Photomultipliers (SIPMs)

Array of Gieger-mode APDs (quench protected) connected to a single output:

Signal = Σ of cells fired

If probability to hit a single cell $< 1 \Rightarrow$ Signal proportional to # photons

Pixel size:
 $\sim 10 \times 10 \mu\text{m}^2$ to $\sim 100 \times 100 \mu\text{m}^2$

Array size:
 $0.5 \times 0.5 \text{ mm}^2$ to $5 \times 5 \text{ mm}^2$

SIPMs (the wave of the future)

Response functions for the SiPMs with different total pixel numbers measured for 40 ps laser pulses

$$N_{firedcells} = N_{total} \cdot \left(1 - e^{-\frac{N_{photon} \cdot PDE}{N_{total}}}\right)$$

Green-red light sensitive APD, low amplitude light signals, U=43V, T=-28 C

SIPM Features

- Photon-counting
- Gain 1E5 – 1E6
- Dynamic range limited by # pixels
- Large temp dependence
- Radiation damage → increase leakage current

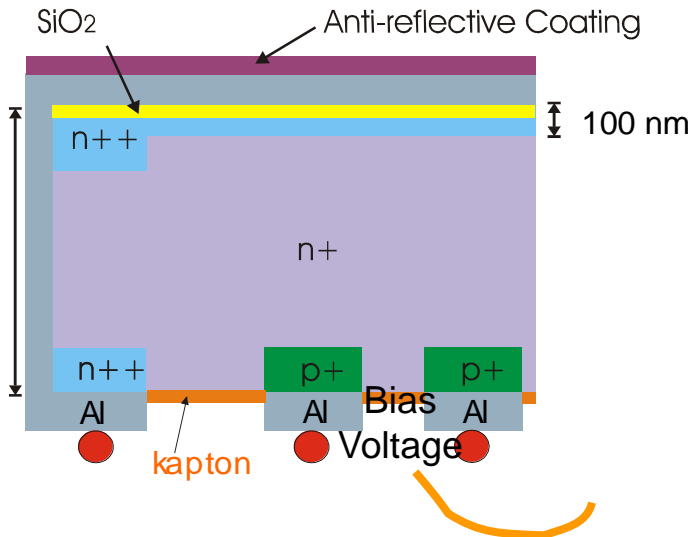

HPD – proximity focussed CMS

Hybrid between pmt and silicon detector.

- Photocathode \rightarrow pe
- 10KV accelerates pe
- 3MV/meter E field
- Impact on silicon \rightarrow gain of 2000
- Can be pixelated
- Can operate in high B field

Diode Structure

HPD Electrostatic focussed LHCb

- HPDs developed for the LHCb RICH
- 80 mm diameter tube has 1024 pixels each $\sim 2.5 \times 2.5 \text{ mm}^2$ at the photocathode
- Uses a silicon sensor with 32×32 pixel array, bump-bonded to a readout chip which can read out the signals fast enough for the LHC (25 ns)

Wire Chamber

A wire chamber is a gas tight container with a wire inside.

The gas is the medium that gets ionized by a passing charged particle.

The wire helps define an electric field and “collects” ionization.

Typical cylindrical wire chamber has:

a wire (anode) held at $+V$

outside of cylinder (cathode) held at ground

Charged particle passing through cylinder creates ions

movement of ions creates a voltage or current pulse

signal pulse travels down wire to “outside world”

usually to preamplifier

Location of charged particle is measured relative to wire

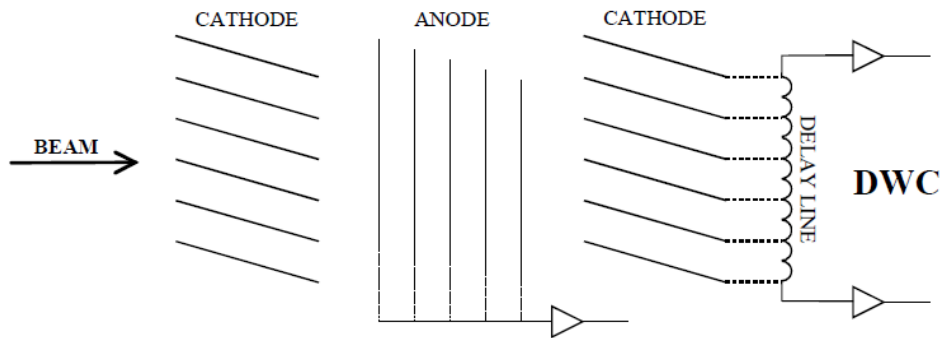

Drift Chambers

CDF Central tracker
drift chamber

“open” low mass geometry. Cathode
formed by field shaping wires

CERN standard
testbeam wire chamber

Cerenkov Effect

- From Relativity, nothing can go faster than the speed of light c (in vacuum)
- However, due to the refractive index n of a material, a particle *can* go faster than the *local* speed of light in the medium $c_p = c/n$
- Analogous to sonic shock wave when airplane travels faster than speed of sound in medium

Cerenkov Effect

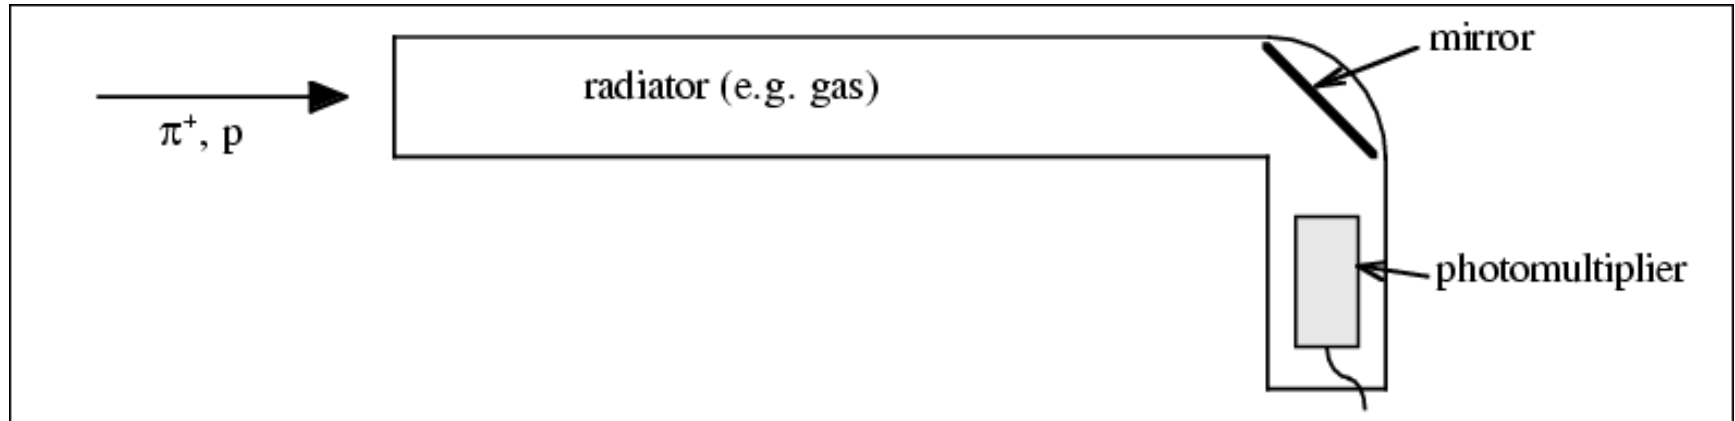

Cerenkov effect same as supersonic shockwave. When particle moves at speed faster than speed of light in medium ($1/n$), generates Cerenkov radiation. Characteristic angle

$$\cos \theta_c = 1/\beta n \quad \text{for } \beta > 1/n$$

Threshold Cerenkov Counters

$$(n - 1) = (n_0 - 1) \cdot \frac{P}{P_0}$$

Approximation of Lorentz – Lorenz Law

$$(n^2 - 1)/(n^2 + 2) = (R/M)\rho$$

Refractive indices vary in the range of 1 to 2.

Material	n	γ_{Th}
glass	1.46 to 1.75	1.22 to 1.37
scintillator	1.4 to 1.6	1.3 to 1.4
water	1.33	1.52
silica aerogel	$1 + (2 \text{ to } 10 \times 10^{-2})$	2 to 5
pentane (at S.T.P.)	$1 + 1.7 \times 10^{-3}$	17
carbon dioxide (at S.T.P.)	$1 + 4.3 \times 10^{-4}$	34
helium	$1 + 3.3 \times 10^{-5}$	123

Aerogel Cerenkov Radiator

Aerogel is solid silica gel. Densities from 0.003 to 0.35 g/cc.

Index of refraction n from 1.00063 to 1.14

Threshold Cerenkov Counters

Cerenkov radiator gas (~10 meters long)

Mylar or Foil Window

Gas Pressure Control

Photomultiplier

JF Primorsko June 2012

Threshold Cerenkov

π/k separation as a function the particle momentum.

For counter with $A = 100$,
 $L = 10$ meters

$$n = 1 + k \frac{\rho}{\rho_{ref}}$$

Index of refraction for gas vs density

$$\beta = v/c = p/E \sim 1 - M^2/(2 * p^2)$$

In a gas with pressure P , the light velocity is given by $v = c/n$, where n is the refractive index.

n is a function of the pressure of the gas. For a given threshold pressure P_{th} , $p/E = c/n(P_{th})$. This threshold pressure is given by

$$P_{th} = (1/2k) * M^2/p^2$$

With k the gas constant

- $k = 3.22 \cdot 10^{-5}$ for Helium,
- $k = 2.99 \cdot 10^{-4}$ for Nitrogen.

Cerenkov Efficiency

Photons are emitted at an angle

$$\theta^2 = 2kP - M^2/p^2$$

and the number of photoelectrons N emitted over a length L (in cm) is approximately

$$N = A L \theta^2$$

$$N_{pe} = \frac{\alpha^2 L}{r_e m_e c^2} \int \epsilon \sin^2 \theta_C dE, \text{ where } \frac{\alpha^2}{r_e m_e c^2} = 370 \text{ cm}^{-1} \text{eV}^{-1}$$

with A depending on quantum efficiencies, inefficiencies of the optical system and so forth. Typical values of A are 100.

$$N \sim 100 L (2kP - M^2/p^2)$$

The efficiency of the counter is then given by

$$\text{Eff} = 1 - e^{-N}$$

Threshold Cerenkov Problem

$$\text{Recall } N = A L \text{ } \varnothing^2$$

Assume $A = 100$ and $L = 10$ meters. P beam = 50 GeV.

The counter is filled with nitrogen gas.

What is the threshold pressure for 50 GeV kaons?

What is the pion efficiency at this pressure?

Differential Cerenkov Counter

A Differential Cerenkov detector only gives a signal for particles with a certain range of β (corresponding, for a given momentum, to a given range in mass).

Ring Imaging Cerenkov (RICH) Counter

Cerenkov light emitted in cone with half-angle θ_c

RICH counters have optics designed to preserve angles of the photons, so measure β

Photon detector is often a multiwire proportional chamber with UV sensitive gas added (TMAE tetrakis dimethylamine ethylene; TEA triethylamine)

Ring Imaging Cerenkov Counter (RICH)

Test beam exposure of RICH to 10 GeV pions. Ring and direct ionization are seen. ~ 27 hits/pion. Gas chamber readout

LHCb pixelated HPD readout

Antiproton production mechanism

$p p \rightarrow p \bar{p} p p$ with $\bar{p} =$ anti-proton

$$(p_b + p_t)^2 = (E_b + m_p, \mathbf{p}_b)^2 = m_b^2 + m_t^2 + 2m_t E_b = 2m_p^2 + 2m_p E_b = (4m_p)^2$$

$$E_b = 7m_p = 6.6 \text{ GeV}$$

Chamberlain Discovery of Antiproton

FIG. 1. Diagram of experimental arrangement.
For details see Table I.

Bevatron protons energy = **6.2 GeV**

Momentum selection to **$v/c = 0.78$**

C1 is veto cerenkov counter, set to have threshold at **$\beta = 0.78$**

C2 is differential cerenkov, **$0.75 < \beta < 0.78$**

S1, S2 TOF counters separated by 40 ft.

CMS HCAL testbeam at CERN

CMS Testbeam Results

Effect of mass in testbeam

Each point would have been Nobel prize! (in 1950's)

Calorimetry

Calorimeter Technique:

Calorimeters are used to measure the energy of particles.

A destructive process where the particle interacts with the calorimeter (showers). The energy of the secondary shower particles measured.

Calorimeter usually divided into active and passive parts:

Active: responsible for generation of signal (e.g. ionization, light)

Passive: responsible for creating the “shower”

Many choices for the “active” material

inorganic crystals (PbWO₄ CMS)

plastic scintillator (CDF, CMS)

liquid scintillator (CCFR)

Noble liquids (argon D0, Atlas)

gas (similar gases as used by wire proportional chambers, CDF Run I)

glass (leaded or doped with scintillator, KTEV)

Many choices for the “passive” material

marble, iron, steel, lead, depleted uranium

Energy Deposition and Showering

Key to calorimetry is the showering process.

In a shower the original particle interacts with the passive material creating many lower energy particles.

The low energy particles deposit energy (via ionization) in the active material.

The amount of ionization (or light) is proportional to the number of amount of energy deposited in the calorimeter.

Cloud chamber photo of an electromagnetic shower. A high energy electron initiates the shower. The electron radiates photons via bremsstrahlung when it goes through the first lead plate. The photons are converted to electrons and positrons by the lead and they in turn create new photons. This process continues until the photons are no longer energetic enough to undergo pair production.

Electromagnetic vs Hadronic Showers

Hadronic showers are more complicated than EM showers

Strong and weak interactions are involved in the hadronic shower process

Energy resolution of hadronic calorimeter usually worse than EM calorimeter

neutrinos leak energy out of calorimeter

muons will not usually be absorbed by calorimeter (unlikely to bremsstrahlung)

long lived particles (K_S , K_L , Λ) may escape calorimeter before decaying (or interacting)

MC simulation of hadronic (proton) and EM shower (photon). Hadronic showers typically have larger lateral spread compared with EM showers.

EM shower

Hadronic shower

Hadron Shower

200 GeV π p Interaction

$$\pi^+, \pi^-, \pi^0$$

$$\langle p_T \rangle_h \sim 0.4 \text{ GeV}$$

Note large multiplicity
And small angle production
→ limited P_T

Sampling Calorimeters

Sampling calorimeters have active and passive material interleaved.

A few typical examples of SC's and their active material are given below.

- Scintillator
- Scintillator with wave shifter readout
- liquid argon with ionization chamber readout
- Gas with MWPC readout

For a)-d) the passive material could be lead or iron.

Energy Resolution

$$\frac{\sigma_E}{E} = \frac{(7.5 - 25)\%}{\sqrt{E}} \quad \text{EM}$$

$$\frac{\sigma_E}{E} = \frac{(35 - 80)\%}{\sqrt{E}} \quad \text{hadronic}$$

Material Properties

	R_L (cm)	E_c (MeV)	λ_a (cm)
Lead	0.56	7.4	17.2
Iron	1.76	20.7	16.8
Tungsten	0.35	8.0	9.6

λ_a = nuclear absorption length

Crystal Calorimeters: fully active

These calorimeters have only active elements (e. g. crystals) that combine a short radiation length with large light output.

NuTeV Detector Hall

NuTeV Charged Current/Neutral Current Separation

Statistical separation of NC and CC events based solely on “event length”:

$$R_{\text{exp}} = \frac{\text{SHORT events}}{\text{LONG events}} = \frac{L \sum_{L < L_{\text{cut}}} L_{\text{cut}}}{L \sum_{L > L_{\text{cut}}} L_{\text{cut}}} = \frac{\text{NC candidates}}{\text{CC candidates}}$$

(measure this ratio in both f and \bar{f} modes)

Generic Collider Detector: Functional Schematic

Collider Experiments: CMS

Total weight 12500 t
 Overall diameter 15 m
 Overall length 21.6 m

~10k CPU cores
 ~2M lines of code

CMS

ECAL 76k scintillating $PbWO_4$ crystals

HO

HCAL Scintillator/brass Interleaved ~15k channels

IRON YOKE

Cathode Strip Ch ~200k wires (CSC)
 Resistive Plate Ch. (RPC)

HF

YBO

YB1-2

YE1-4

- Pixel Tracker
- ECAL**
- HCAL**
- Muons
- Solenoid coil

- Pixels ($100 \times 150 \mu m^2$) ~ 1 m² 66M channels
- Silicon Microstrips ~ 210 m² 9.6M channels

Tracker

Drift Tubes (DT) 170k wires and Resistive Plate Chambers (RPC)

Supersymmetry

► Gluinos and squarks are strongly produced (cross sections as high as a few pb for masses as high as 1 TeV)

• they decay through cascades to the **Lightest SUSY Particle (LSP)** $\tilde{\chi}_1^0$

• combination of jets, leptons, E_T^{miss}

Look for deviation from SM

multijets and E_T^{miss}

Always 2 LSP if R parity is conserved

How to design an experiment—supersymmetry at collider

- ⊕ A key signature is jets and missing E_t
- ⊕ How to measure a jet
- ⊕ What can cause missing E_t
 - ⊞ Neutrinos
 - ⊞ Undetected muons
 - ⊞ Cracks and defects in calorimetry
 - ⊞ Lack of total coverage in 4π (beampipe)
 - ⊞ Energy mismeasurement by calorimeter

Jets – Cone Algorithm

CONE center - (η^C, φ^C)

CONE $i \in C$ iff $\sqrt{(\eta^i - \eta^C)^2 + (\varphi^i - \varphi^C)^2} \leq R$

Energy $E_T^C = \sum_{i \in C} E_T^i$

Many ways to define cluster in calorimetry.

Newer algorithm \rightarrow particle flow.
Use full information from detector

Particle Flow Jets (the future)

- ✦ In a typical jet:
 - ✦ 60 % of jet energy is from charged hadrons
 - ✦ 30 % from photons (mainly from π^0)
 - ✦ 10 % from neutral hadrons (n and K_L^0)

- ✦ The traditional approach to jet reconstruction:

Measure all of jet energy in calorimeters

→ ~ half of energy measured in HCAL

Poor HCAL resolution limits jet energy resolution: $\Delta E/E \sim 60\% / \sqrt{E}$

- ✦ Particle Flow approach:

- ✦ Charged particles well measured in tracker
- ✦ Photons in ECAL
- ✦ Neutral hadrons (only) in HCAL

→ Only 10 % of jet energy taken from HCAL

$\Delta E/E \sim 30\% / \sqrt{E}$ may be achieved

Particle-flow calorimetry

- ✦ The main remaining contribution to the jet energy resolution comes from the confusion of contributions, from overlapping showers etc
- ✦ Most important is to have high *granularity* of calorimeters to help the (complicated) pattern recognition
- ✦ This is the approach being studied for detectors at the future e^+e^- linear collider (ILC or CLIC)
- ✦ A motivation for CMS HCAL upgrade

Simulated event in
an ILC detector

Calorimeters and Neutrinos/photinos

Missing E_T is a global variable

$$dE/E \sim a/\sqrt{\Sigma(E_T)}$$

summed over all E_T in the event

Missing E_T significance

$$S = E_T / \sqrt{\Sigma E_T}$$

Energy Containment for pions vs int length

For 95 % containment, the
Fluctuation in the leakage is
➤ 5 %.

With 7λ total depth, single pions are
➤ 95 % contained for energies < 100 GeV
As the LHC is a 7 TeV + 7 TeV machine,
That is a bit thin.

Missing Et due to leakage, pion non-interaction (0.001 for 7λ), cracks

Particle identification through ionization losses

$$p = m\beta\gamma$$

$$\frac{dE}{dx} \propto \frac{1}{\beta^2} \ln(\beta^2\gamma^2)$$

Simultaneous measurement of p and dE/dx defines m .

π/K separation at a 2σ level requires a dE/dx resolution in the range of 2 to 3% - depending on the momentum range

**But:
Large fluctuations
and Landau tails !**

Average energy loss in
80/20 Ar/CH₄ (NTP)

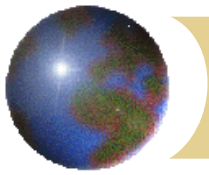

Distribution of Energy Loss

Amount of energy lost from a charged particle going through material can differ greatly from the average or most probable

Figure 3.9: The Landau distribution of the total energy loss across a gas volume. Note the long *Landau tail* on the distribution.

The long tail of the energy loss distribution makes particle ID using dE/dx difficult.
To use ionization loss (dE/dx) to do particle ID typically measure many samples and calculate the average energy loss using only a fraction of the samples.

dE/dx in OPAL Jet Chamber

The chamber is 4 m long with an inner diameter of 0.5 m and an outer diameter of 3.7 m. The sensitive volume is divided into 24 identical sectors, each containing a plane with 159 sense wires.

Jet Chamber

Transition Radiation

- TR is emitted when a charged particle traverses the boundary between two media with different dielectric constants ϵ_1 and ϵ_2 . Related to cerenkov light $n = \sqrt{\epsilon_r \mu_r}$
- TR is the result of the reformation of the particle's field when traveling from a medium with ϵ_1 to a medium with ϵ_2
- TR is not related to the charge acceleration ($v = \text{const}$)
- $\Delta E \sim \gamma$. For a 10 GeV electron, $\gamma \sim 2 \times 10^4$, $\Delta E \sim \text{keV}$
- Radiation probability low (1%) so need many layers of radiator.
- Radiation emitted in the very forward direction, in cone of angle $1/\gamma$ around the particle direction \rightarrow photons will be seen in same detector as the ionization from the track

Transition Radiation Detector

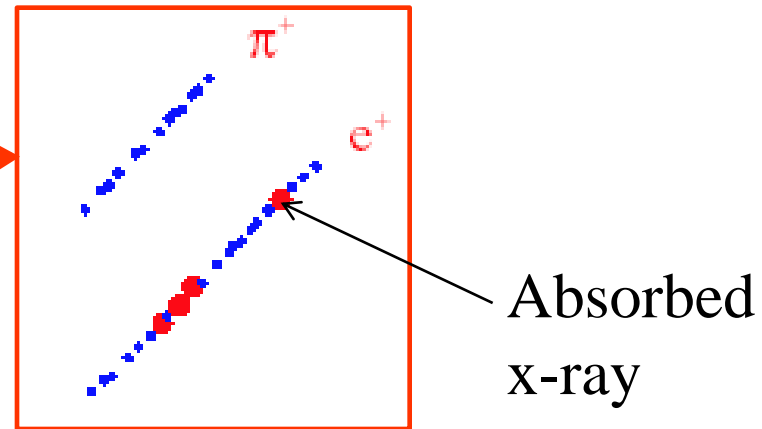

Fig. 2.4. Number of detected TR photons as a function of the radiator foil thickness, for given radiator length and allowed amount of material. The curve shown results from a smoothing algorithm.

The radiator is made of a low atomic number material, to minimise absorption of the X-ray photons. Lithium foils in a helium atmosphere is ideal, for example 400 foils of thickness 40 microns, spaced 160 microns apart by corrugations on alternate foils.

ATLAS TRT (Transition Radiation Tracker) -30000 channels

AMS-02 on ISS: Measure Cosmic ray species

Last Topic: Magnetic Monopoles

Charge of Monopole $n \cdot 137$ times larger than electron \rightarrow very heavily ionizing

$$\mathbf{F} = g \left(\mathbf{B} - \frac{1}{c^2} \mathbf{V} \times \mathbf{E} \right)$$

Lorentz force for magnetic monopole. Gains energy by falling through magnetic field.

Magnetic Monopole Exercise: calculate Dirac Quantization Relation

Dirac Quantization Relation

$$g e = \frac{\hbar c}{2} n, n = 1, \dots$$

$$\mathbf{B} = g \frac{\mathbf{r}}{r^3}$$

$$F_y = \frac{ev}{c} B_x = \frac{eg}{c} V \frac{b}{(b^2 + V^2 t^2)^{3/2}}$$

rotation around x axis

$$\Delta P_y = \frac{egVb}{c} \int_{-\infty}^{+\infty} \frac{dt}{(b^2 + V^2 t^2)^{3/2}} = \frac{2eg}{cb}$$

$$\Delta L = b \Delta P_y = \frac{2eg}{c} = n\hbar \rightarrow eg = \frac{\hbar c}{2} n \text{ assuming quantized angular momentum.}$$

Monopole Experiments

◆ Cosmic Rays

-Price reported event from 18 m² plastic detector in 1975. Later excluded by Alvarez. Then they published an upper limit.

◆ Moon Rocks

-One of the first scientific experiments with moon rocks was to search for a concentration of magnetic monopoles by Alvarez.

How to design an experiment—magnetic monopoles at collider

- At general purpose experiments like ATLAS, CMS you can “design” your own specialized experiment.
- You know the experiment, operation of the subdetectors
- You know how your signal (monopole) is produced (MC) and interacts (Geant)
- Design the trigger you need. (Maybe existing trigger path?)
- Design the analysis using details of particle interaction in your experiment.
- Monopole bends “wrong way” in magnetic field
- Accelerated by magnetic field
- Loses energy very rapidly in matter

Trigger	Threshold (GeV or GeV/c)	Rate (Hz)	Cumulative Rate (Hz)
Inclusive electron	29	33	33
Di-electrons	17	1	34
Inclusive photons	80	4	38
Di-photons	40, 25	5	43
Inclusive muon	19	25	68
Di-muons	7	4	72
Inclusive τ jets	86	3	75
Di- τ jets	59	1	76
1 jet * E_T^{miss}	180 * 123	5	81
1 jet OR 3 jets OR 4 jets	657, 247, 113	9	89
Electron * Jet	19 * 45	2	90
Inclusive b jets	237	5	95
Calibration etc. (10%)		10	105
TOTAL			105

Detectors: Things don't always go as planned

CMS HCAL – Fiber Readout of Scintillator

One 0.94 mm fiber per tile (4 from HO)

Optical grouping into readout depths

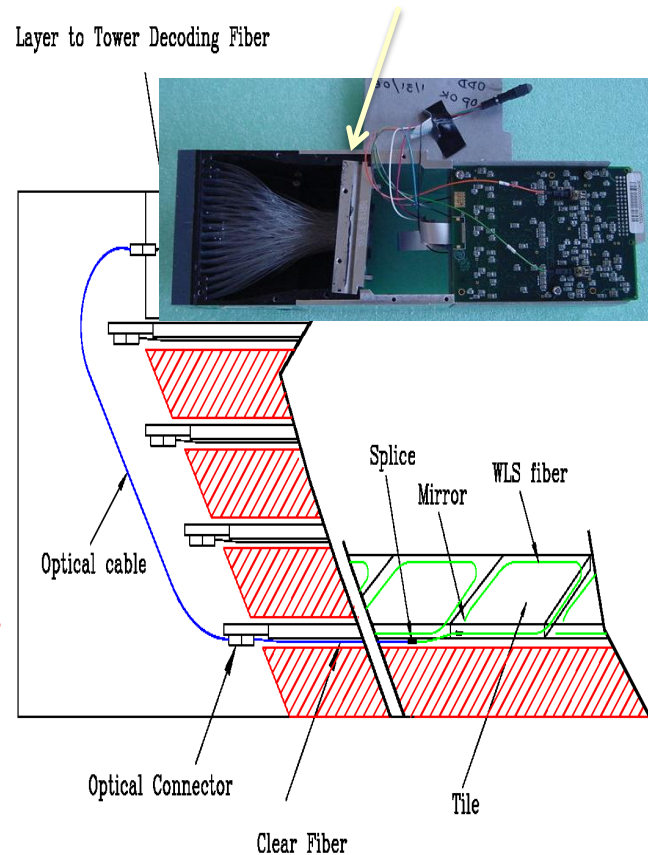

Barrel Readout Module

~71,000
Barrel/Endcap
0.94 mm fibers

~670 cm² total
photodetection
area

Layer to Tower Decoding Fiber

Hybrid Photo-diode (HPD)

- QE ~ 15%
- Gain 1500 ~ 2000 depending on voltage
 - Running at high voltage, 7~8kV
- optical-to-HPD mapping (ODU)

Problems: HPD

- HPD was a long development path for CMS HCAL
- No existing photodetector worked in 4T with enough gain. (20pe/GeV)
- HPDs tested extensively for planned operating environment, E parallel to B, B = 4T (and at B=0T)
- No problems found
- But – In real CMS B field was not as modeled: E not completely parallel. Also not tested at intermediate field (worked at 0 and 4T)
- We discovered that there were problems

SIPM “Drop-in” replacement for HPD

- Using Hamamatsu 3mm x 3mm, 50 μm pitch, SiPM, we can mimic the layout of the HPD.
- These are coupled to the existing optical decoders and read out using the same ADC.

CMS Forward calorimeter HF

HF is located about 11 m from the interaction point, covers $3 < |\eta| < 5$ with depth $10 \lambda_{\text{int}}$

Consists of iron absorber embedded with quartz fibers parallel to the beam direction in a 5x5 mm matrix

Charged particles from showers produce Cherenkov light

HF signal generation and collection is very fast ~10 ns

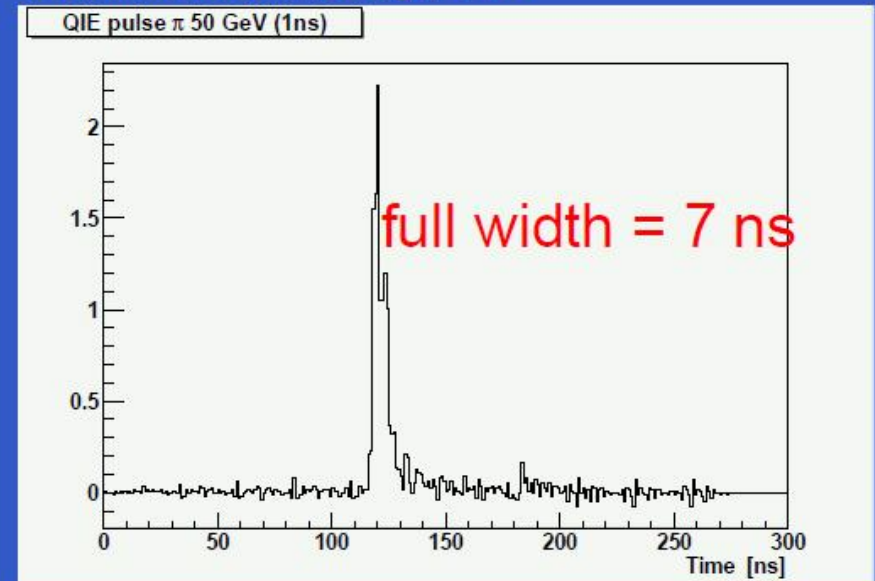

CMS HF Calorimeter

Quartz-fiber Čerenkov calorimeter

First device of its kind.
200k quartz fibers.

Test beam results Aug. 2003

Readout: 2000 pmts

HF side view

Fiber bundles

Each calorimeter tower has two PMTs: one reading bundle of **LONG** fibers, the other **SHORT** fibers (143cm), for some EM/HAD separation

PMTs

Light guides

Readout Box

IP

HF PMT : Abnormal Events

150GeV Muon / Wedge 2-6

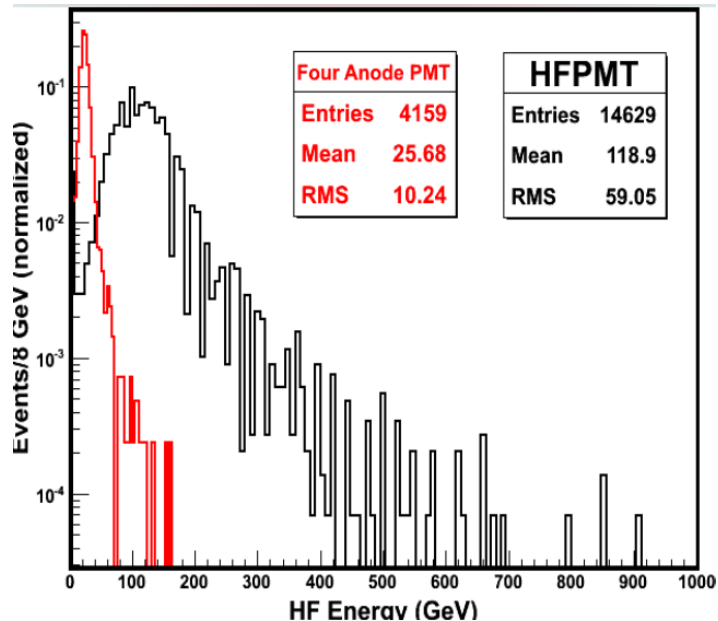

- ⊕ These events are most likely to be from Cerenkov radiation from particles directly hitting the PMT window.
 - ⊕ peak of muon signal ~ 200 GeV
- ⊕ The glass window is plano-convex.
 - ⊕ 2mm thick in center
 - ⊕ 6.1mm thick at the edge

TB2004 elog 3601 Aug. 2, 2004

MIP Cerenkov light in HF

It was discovered that minimum-ionizing tracks hitting the pmt front window created cerenkov light, large false signals.
Solution → replace pmts with thin window pmt

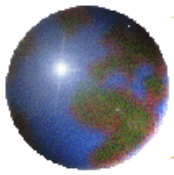

Window: ~2 mm thick at the center, ~6 mm thick at the edges.

R7600U-200-M4

Four Anode Square PMT

Window: < 1 mm thick

Now that you know detectors, I need...

Scintillating fiber trigger counter

3mm fiber diameters

6mm wide, ~20 cm long

2 of them for SIPM test beam at CERN
in October.

LHCb overview

interaction
region

Large Hadron Collider

- ⊕ pp collisions: $\sqrt{s} = 14 \text{ TeV}$
- ⊕ bunch crossing every 25 ns

LHCb

- ⊕ Studies physics of b-flavoured hadrons (CP violation)
- ⊕ B-hadrons produced at small angles
 - ⊕ -> Single arm forward spectrometer
- ⊕ 10 – 300 (250) mrad in bending plane (non bend.)
- ⊕ Luminosity $2 - 3.5 \times 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$

6/18/2012

Jim Freeman

In-time pileup events

$\langle n \rangle \approx 33$ for highest luminosity in 2012
-> challenges to trigger and computing!

$$P_n = \frac{(n)^n}{n!} e^{-n}$$

Vertex resolution better than $\sim 200 \mu\text{m}$ (CMS), $\sim 100 \mu\text{m}$ (LHCb), vertices a few cm apart, beam spot size $16 \mu\text{m}$ at collision point. Average number of interactions at nominal LHC luminosity and 25 ns bunch spacing: 23.

Jim Freeman

LHCb luminosity leveling

✦ Luminosity leveling

- LHCb already running above design lumi
 - Average $L \sim 3 \times 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$ (nominal 2×10^{32})
- Need to cope with higher occupancies
 - More pile-up: average ~ 1.5 (nominal 0.5)
- Continuous, automatic adjustment of offset of colliding beams.
- Allows optimal conditions throughout a fill.

Silicon microstrip modules, vertex

Pileup veto trigger

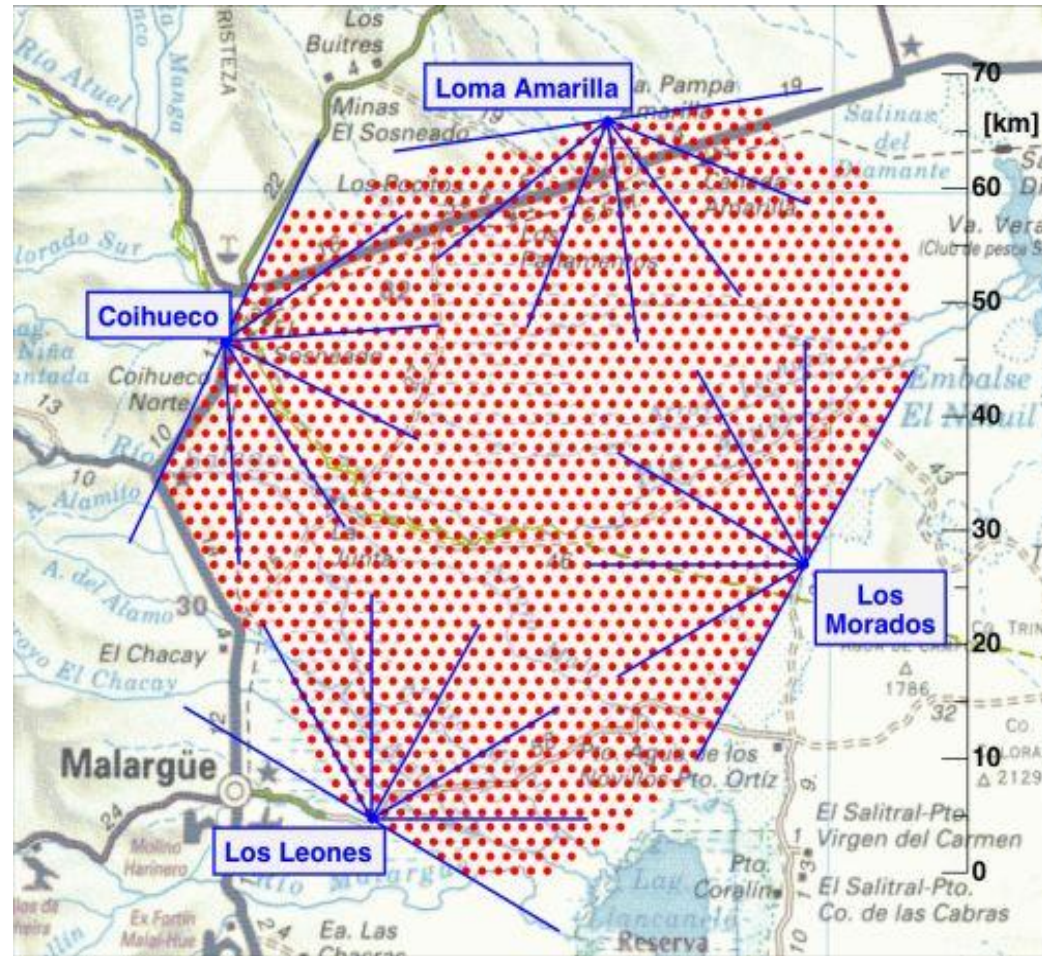

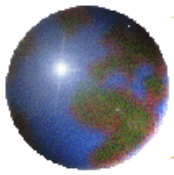

- ⊕ 21 stations with $R-\Phi$ geometry
 - ⊞ Fast R-Z tracking in trigger farm
 - ⊞ Overlap of right and left det. halves
 - ⊞ Total of 176k strips
- ⊕ 2 stations with R-sensor for L1 PileUp trigger

Auger Experiment - Argentina

- ➊ Detector field: 3000 km²
- ➋ 24 Fluorescence cameras on 4 observations points
- ➌ 1600 Surface detectors (1.5 km spacing)

Fluorescence detector

- ✦ Charged particles in an air shower also interact with atmospheric nitrogen (excitation)
- ✦ Emitted ultraviolet light via a process called fluorescence
- ✦ Direction and energy of the cosmic particle can be determined

Fluorescence detector

Surface detector

Surface detector

- ✦ Base of detector = 10m^2
- ✦ 12 tons of very pure water as detection material
- ✦ 3 Photomultipliers detect cerenkov signals
- ✦ With GPS antenna high time correlation to different detectors
- ✦ Energy given in VEM (Vertical Equivalent Muon)

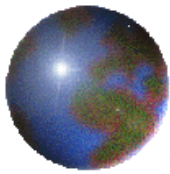

Combination of FD and SD

Results

Auger Results
