

# QCD HIGHER-ORDER CORRECTIONS: CURRENT STATUS AND PROSPECTS

Costas G. Papadopoulos

INPP, NCSR “Demokritos”, 15310 Athens, Greece

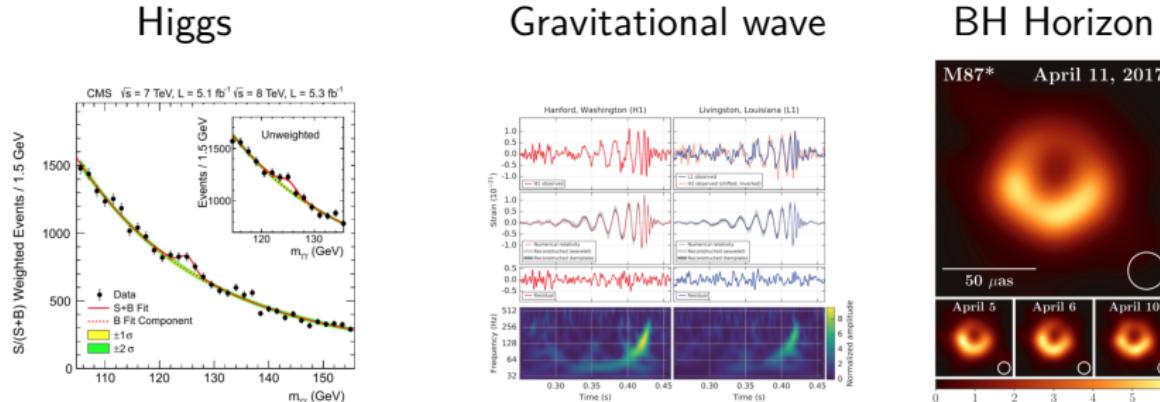

HOCTools-II

Workshop on Future Accelerators, April, 23-29, 2023

# OUTLINE

- ① Introduction: what calculations we need
- ② LO: from Feynman diagrams to recursive equations
- ③ The NLO revolution: from Feynman Integrals to integrands
- ④ Towards higher precision: NNLO  $2 \rightarrow 3$ ,  $N^3LO$   $2 \rightarrow 2$
- ⑤ Summary - Discussion

# INTRODUCTION

**Fig. 3.** The diphoton invariant mass distribution with each event weighted by its category. The lines represent the fitted background and signal, and the coloured bands represent the  $\pm 1$  and  $\pm 2$  standard deviation uncertainties in the background estimate. The inset shows the central part of the unweighted invariant mass distribution. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this Letter.)

**FIG. 1.** The gravitational-wave event GW150914 observed by the LIGO Hanford (H1, left column) and Livingston (L1, right column) detectors. Times are shown relative to September 14, 2015 at 09:53:51 UTC. For visualization, all time series are filtered with a bandpass of 20–200 Hz. Top row: raw data. Second row: data after applying a bandpass filter and a Butterworth filter to remove the strong instrumental spurious lines seen in the Fig. 1 spectra. Top row, left: H1 strain. Top row, right: L1 strain. GW150914 was a binary black hole merger event. The signal is a chirping waveform that increases in frequency and amplitude over time and reversed its phase for the detectors' relative orientation. Second row: Gravitational-wave signals projected onto each detector in the 35–390 Hz band. Solid lines show a numerical relativity waveform for a system with parameters consistent with those measurements. Shaded regions indicate the uncertainty of the waveform. The red shaded region corresponds to the signal amplitude required to excite two independent waveform reconstructions. One (dark gray) mode is the signal using binary black hole template waveforms [29], the other (light gray) mode is the signal using a numerical relativity waveform [30]. Bottom row: Frequency spectrum of the signal for one Gaussian waveform [40,41]. These reconstructions have a 95% overlap, as shown in [19]. Third row: Results after subtracting the filtered numerical relativity waveform from the filtered detector time series. Shown row: A time-frequency representation [42] of the signal data, showing the signal frequency increasing over time.

**FIG. 3.** Top: BTU image of M87\* black-hole observations on 2017 April 11 as a representative example of the images collected in the 2017 campaign. The image is the average of three different imaging methods after convolving each with a different kernel. The size of the central black hole is indicated by the radius of the outermost ring. The radius of the outermost ring of the three kernels (20 arcsec FWHM) is shown in the lower right. The image is shown in units of brightness temperature,  $T_b = S^2/2k_1$ , where  $S$  is the flux density. A color bar indicates the brightness temperature. Middle: Time evolution of the angle of the resolution element. Bottom: similar images taken over different days showing the stability of the basic image structure and the equivalence among different days. North is up and east is to the left.

# INTRODUCTION

LHC

LIGO

EHT

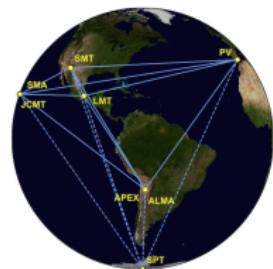

Figure 1. Eight stations of the EHT 2017 campaign over six geographic locations as viewed from the equatorial plane. Solid baselines represent mutual visibility on M87\* (+12° declination). The dashed baselines were used for the calibration source J2239 (see Pages 11 and 15).

# INTRODUCTION

LHC

LIGO

EHT

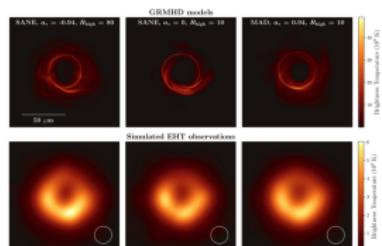

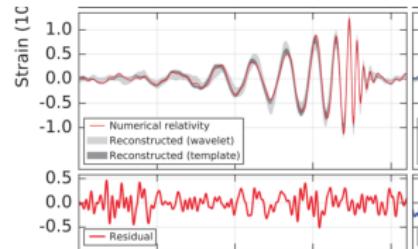

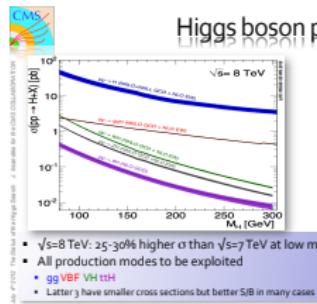

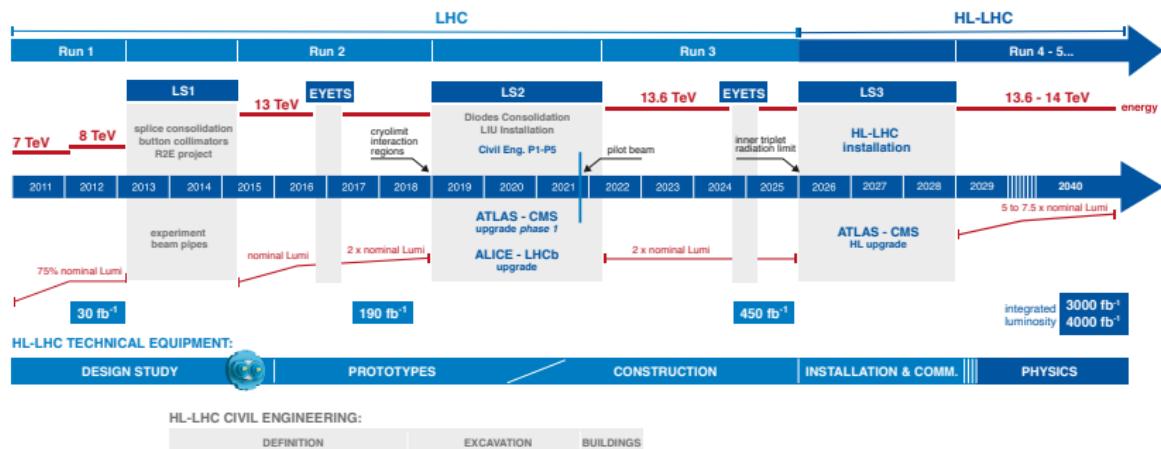

Figure 4. Top three example models of some of the best-fitting sources from the image library of GRMHD simulations for Sprial 11 corresponding to different spin parameters and accretion flows. Bottom: the same theoretical models, processed through a VLBI simulation pipeline with the same schedule, telescope characteristics, and noise properties as the real observations. The images are reconstructed using the same template as the real observations. The images are reconstructed using the same template as the real observations. This highlights that a single good fit does not imply that a model is preferred over others (see Paper I).

# FCC-EE THEORY

→Marek Schönherr

Process	Theory	Monte-Carlo
Z-pole	NNLO EW needed throughout (N3LO in some places) including ISR, FSR resummation and initial-final interference (IFI)	highest precision Monte-Carlo event generators to account for finite fiducial region, bremsstrahlung effects, hadronisation corrections, etc.
WW-threshold	needs precision calculation (NNLO QCD, QCD-EW, EW) and QED threshold resummation	including implementation in Monte-Carlo event generators to account for finite ?fiducial region, colour reconnection, hadronisation, etc.
ZH-threshold	direct access to all Higgs decay channels incl. $h \rightarrow gg$ and $h \rightarrow \text{inv.}$	Monte-Carlo event generators with highest precision for both production mechanisms and Higgs decays necessary
$t\bar{t}$ -threshold	needs precision calculation (NNLO QCD, QCD-EW) and QED+QCD threshold resummation	implemented in Monte-Carlo event generators to account for finite fiducial region, top decay kinematics, colour reconnection, hadronisation, etc.

Besides QCD, complicated EW and demanding QED corrections!

$$\begin{aligned} N(q) &= \sum_{i_0 < i_1 < i_2 < i_3}^{m-1} \left[ d(i_0 i_1 i_2 i_3) + \tilde{d}(q; i_0 i_1 i_2 i_3) \right] \prod_{i \neq i_0, i_1, i_2, i_3}^{m-1} D_i \\ &+ \sum_{i_0 < i_1 < i_2}^{m-1} \left[ c(i_0 i_1 i_2) + \tilde{c}(q; i_0 i_1 i_2) \right] \prod_{i \neq i_0, i_1, i_2}^{m-1} D_i \\ &+ \sum_{i_0 < i_1}^{m-1} \left[ b(i_0 i_1) + \tilde{b}(q; i_0 i_1) \right] \prod_{i \neq i_0, i_1}^{m-1} D_i \\ &+ \sum_{i_0}^{m-1} \left[ a(i_0) + \tilde{a}(q; i_0) \right] \prod_{i \neq i_0}^{m-1} D_i \end{aligned}$$

# THE ONE-LOOP CALCULATION IN A NUTSHELL

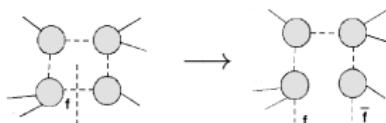

The computation of  $pp(p\bar{p}) \rightarrow e^+ \nu_e \mu^- \bar{\nu}_\mu b\bar{b}$  involves up to six-point functions.

The most generic integrand has therefore the form

$$\mathcal{A}(q) = \sum \underbrace{\frac{N_i^{(6)}(q)}{\bar{D}_{i_0} \bar{D}_{i_1} \cdots \bar{D}_{i_5}}}_{\text{Diagram 1}} + \underbrace{\frac{N_i^{(5)}(q)}{\bar{D}_{i_0} \bar{D}_{i_1} \cdots \bar{D}_{i_4}}}_{\text{Diagram 2}} + \underbrace{\frac{N_i^{(4)}(q)}{\bar{D}_{i_0} \bar{D}_{i_1} \cdots \bar{D}_{i_3}}}_{\text{Diagram 3}} + \underbrace{\frac{N_i^{(3)}(q)}{\bar{D}_{i_0} \bar{D}_{i_1} \bar{D}_{i_2}}}_{\text{Diagram 4}} + \dots$$

In order to apply the OPP reduction, HELAC evaluates numerically the numerators  $N_i^6(q), N_i^5(q), \dots$  with the values of the loop momentum  $q$  provided by CutTools

- generates all inequivalent partitions of 6,5,4,3... blobs attached to the loop, and check all possible flavours (and colours) that can be consistently running inside
- hard-cuts the loop ( $q$  is fixed) to get a  $n + 2$  tree-like process

The  $R_2$  contributions (rational terms) are calculated in the same way as the tree-order amplitude, taking into account extra vertices

# NNLO 2→3

NNLO QCD:  $pp \rightarrow \gamma\gamma\gamma + X$   
leading-colour approximation for double-virtual

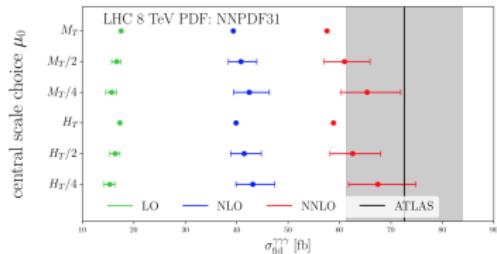

Figure 1. Predictions for the fiducial cross-section in LO (green), NLO (blue) and NNLO (red) QCD versus ATLAS data (black). Shown are predictions for six scale choices. The error bars on the theory predictions reflect scale variation only. For two of the scales only the central predictions are shown.

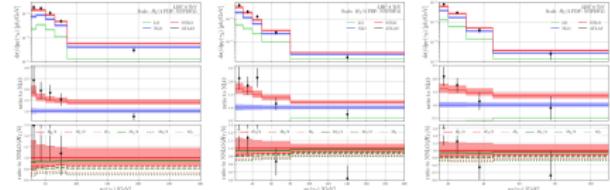

Figure 2.  $p_T$  distribution of the hardest photon  $\gamma_1$  (left),  $\gamma_2$  (center) and the softest one  $\gamma_3$  (right). Top plot shows the absolute distribution at NNLO (red), NLO (blue) and LO (green) versus ATLAS data (black). Middle plot shows same distributions but normalized to the NLO. Bottom plot shows central NNLO predictions for 6 different scale choices (only the central scale is shown) with respect to the default choice  $\mu_0 = H_T/4$ . The bands represent the 7-point scale variations about the corresponding central scales.

# NNLO $2 \rightarrow 3$

## NNLO QCD: $pp \rightarrow \gamma\gamma\gamma + X$ leading-colour approximation for double-virtual

fiducial setup for  $pp \rightarrow \gamma\gamma\gamma + X$ ; used in the ATLAS 8 TeV analysis of Ref. [37]

$p_{T,\gamma_1} \geq 27 \text{ GeV}, \quad p_{T,\gamma_2} \geq 22 \text{ GeV}, \quad p_{T,\gamma_3} \geq 15 \text{ GeV}, \quad 0 \leq |\eta_1| \leq 1.37 \text{ or } 1.56 \leq |\eta_1| \leq 2.37,$   
 $\Delta R_{\gamma\gamma} \geq 0.45, \quad m_{\gamma\gamma\gamma} \geq 50 \text{ GeV}, \quad \text{Frixione isolation with } n = 1, \delta_0 = 0.4, \text{ and } E_T^{\text{ref}} = 10 \text{ GeV}.$

Table 1: Definition of phase space cuts.

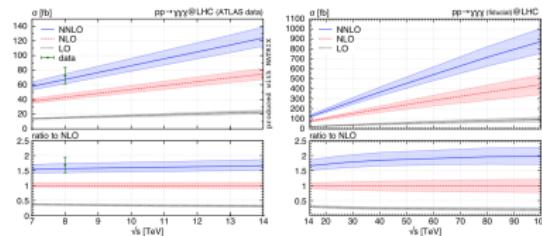

Figure 4: Fiducial cross sections for  $pp \rightarrow \gamma\gamma\gamma + X$  as a function of the centre-of-mass energy at LO (black dotted), at NLO (red dashed), and at NNLO (blue, solid). The green data point at 8 TeV corresponds to the cross section measured by ATLAS in Ref. [37].

→ S. Kallweit, V. Sotnikov and M. Wiesemann, Phys. Lett. B 812 (2021) 136013

# NNLO 2→3

NNLO QCD:  $pp \rightarrow 3\text{jets} + X$   
leading-colour approximation for double-virtual

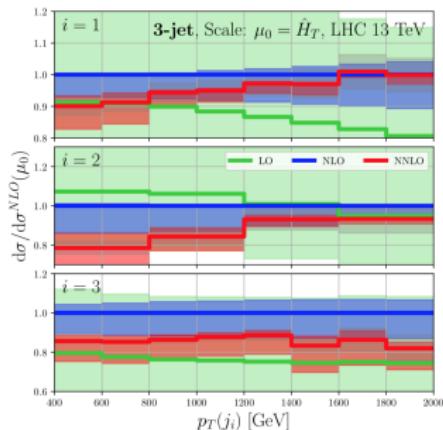

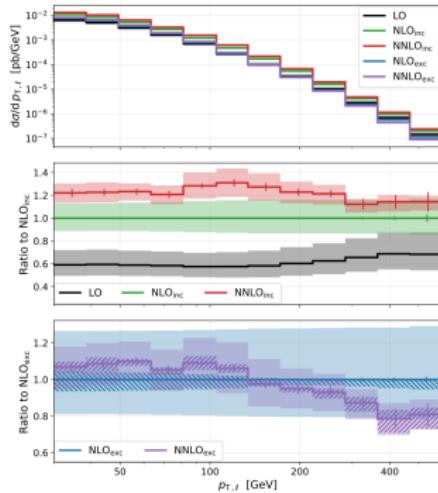

FIG. 1: The three panels show the  $i$ th leading jet transverse momentum  $p_T(j_i)$  for  $i = 1, 2, 3$  for the production of (at least) three jets. LO (green), NLO (blue) and NNLO (red) are shown for the central scale (solid line). 7-point scale variation is shown as a coloured band. The grey band corresponds to the uncertainty from Monte Carlo integration.

→ M. Czakon, A. Mitov and R. Poncelet, Phys. Rev. Lett. **127** (2021) no.15, 152001 [[arXiv:2106.05331 \[hep-ph\]](https://arxiv.org/abs/2106.05331)].

*n-particle, 2-loop Amplitude* → *(n+2)-particle, 1-loop Amplitude*

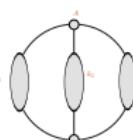

- 1) Definition of the flavor of the  $n + 1$  and  $n + 2$  particles.
- 2) Generation of the  $n + 2$  color-states (( $n + 2$ )!, Color-Flow Representation).
- 3) Generation of Blob-Topologies.
- 4) Cut of the topologies in the  $k_3$ -line (middle-line) → the 2 extra particles.
- 5) Flavor-Color Dressing of the 1-loop loop-particles.
- 6) Second cut of the blob-topology → tree-level graph ( $n + 4$  color-states).
- 7) Creation of currents contributing to the configuration (Dyson-Schwinger to blobs).
- 8) Reduction of the  $n + 4$  color-states to  $n$  and identification of  $N_C$  power.
- 9) Storing of the numerator information to the Skeleton.

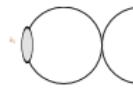

# TWO-LOOP BLOB-TOPOLOGIES

- Binary representation for the particles: e.g. for  $n = 4$ ,  $\{1, 2, 3, 4\} \rightarrow \{1, 2, 4, 8\}$
- What a blob and its level are?

- List representation for the 3 grand blob-topologies:

*Theta-topologies:*   $\equiv \{\{k_1\}, \{k_2\}, \{k_3\}, \{A\}, \{B\}\}$

*Infinity-topologies:*   $\equiv \{\{k_1\}, \{k_2\}\}$

*Dumbbell-topologies:*   $\equiv \{\{k_1\}, \{k_2\}, \{C\}, \{A\}, \{B\}\}$

# NUMERATORS AND NUMERICS IN 4 DIMENSIONS

Process	loop-flavors	Color	Size	Time	Numerators
$gg \rightarrow q\bar{q}$	$\{g, gh, \bar{g}h, q, \bar{q}\}$	full	16.1 MB	3m 14.509s	13856

$P_3 (g_{84})$	22 (12)	132 (90)	1196 (692)	4566 (2488)

TABLE: Number of GP entering in the solution. In parenthesis we give the corresponding number for the non-zero top-sector basis elements.

- with timings, running the GiNaC Interactive Shell ginsh, given by 1.9, 3.3, and 2 seconds for  $P_1$ ,  $P_2$  and  $P_3$  respectively and for a precision of 32 significant digits
- A very different canonical basis, several elements start at  $\epsilon^4$ .

# SUMMARY & OUTLOOK

- Non-planar families

- We have completed the hexa-box families,  $N_1$ ,  $N_2$ ,  $N_3$ .
- Checks against known results successful.
- Next task: double-pentagon families,  $N_4$ ,  $N_5$ .

- SDE approach: all MI up to 4-point with up to 2 off shell legs and 5-point with up to one off-shell leg.

- Speed-up numerical evaluation

- Improving GPLs analytic continuation.
- Study letters ordering in physical regions, use different mappings and/or fibrations.
- Combine analytics with numerics → one-dimensional integral representation

- Massive internal particles.

→ N. Syrracos, [arXiv:2303.07395 [hep-ph]].

- **HELAC2LOOP**: generic approach to amplitude reduction and evaluation

# SUMMARY & OUTLOOK

- Non-planar families
  - We have completed the hexa-box families,  $N_1$ ,  $N_2$ ,  $N_3$ .  
→ A. Kardos, C. G. Papadopoulos, A. V. Smirnov, N. Syrrakos and C. Wever, JHEP 05 (2022), 033
    - Checks against known results successful.
    - Next task: double-pentagon families,  $N_4$ ,  $N_5$ .

# EXPLAIN THEORY

- The known knowns

Newtonian gravity, Electromagnetism, QM, QFT, Einstein gravity,  
and a large part of the SM

→ experimental input + "perturbative" calculations

- The known unknowns

Dark matter, dark energy, asymmetries, the rest of the SM,  
plus many others, such as BH, strongly interacting matter, etc.

# EXPLAIN THEORY

- What we can promise is to get all elements, a highly non-trivial task, accelerators, detectors, calculations, education, etc. to fully exploit the experimental data, so to unambiguously determine any deviation from the known knowns
- and many models (complete or incomplete) that may accommodate such deviations, i.e. discoveries.
- not excluding the unknown

→ this is not different from what other scientific fields are pursuing or the history of sciences dictates
