# Appendix: More technological details

# Appendix: More technological details

## Collecting the data

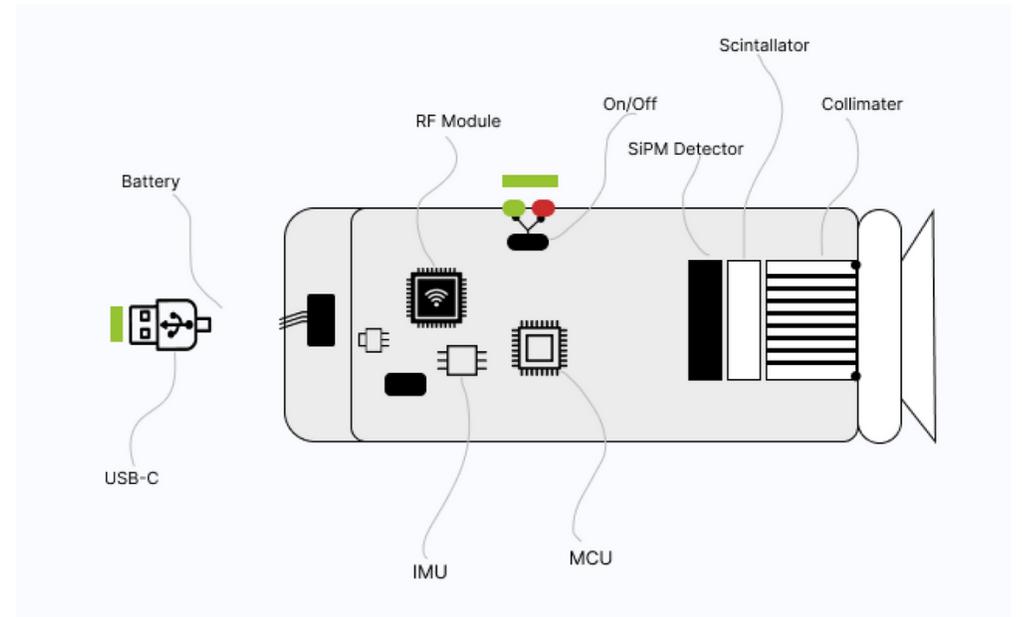

- The Collimator, Scintillator and SiPM detector are included in the POSICS2 camera. Together, they detect gamma and beta rays. This is useful for differentiating between tumorous cells and healthy cells.
- The IMU contains an accelerometer, magnetometer and gyroscope which in combination with sensor fusion algorithms is capable of precisely determining the orientation of the device in real time.
- The device is based around an MCU and an RF module which transfer the orientation, position and image data to the PC. The device has a button and a LED to serve as a minimal user interface.

## Transmission

As LUMO is wireless device, the RF module can be configured as a WIFI access point or client, and it connects to the computer using a custom protocol over TCP.

## Device Details

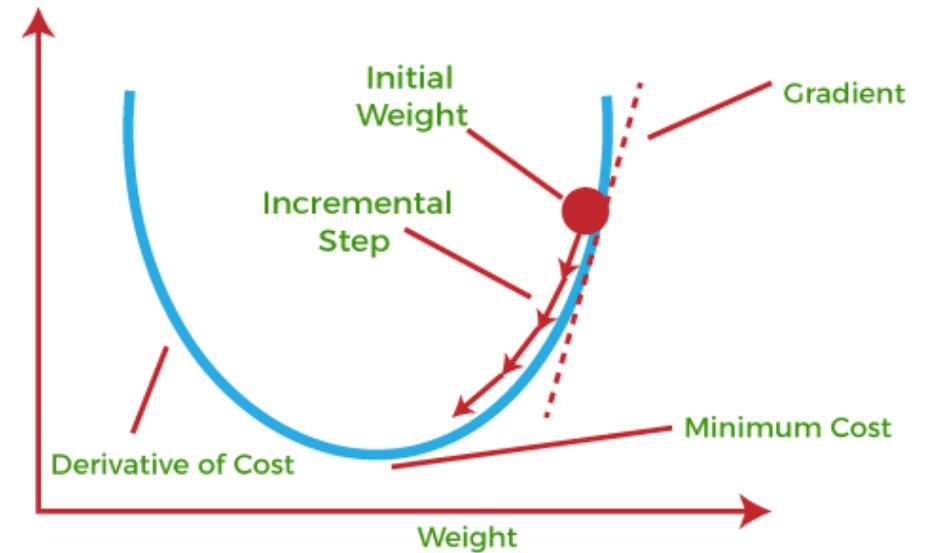

- Battery
- The USB-C connector is necessary to charge the device.
- There is a LEDs that indicates the state of the device.

# Appendix: More technological details

## Software

- It computes the projection of the points captured by the POSICS2 camera and represents them both in 3D and in a 2D scatter.
- Then, once it receives some collisions it calculates the mean and shape of that scan, and after a beep, the camera should moved to another position.
- From every scan, the software extracts a line which passes through the mean and goes in the perpendicular direction of the plane of the camera.
- Once some lines are computed, it finds the point at minimum distance of all the lines. That's where the tumour will be located.
- Next, with the Gradient Descent algorithm we improve the position.
- Lastly, we plot the 3D representation of the tumour in the digital body.
- At the moment, in order to capture the points accurately, the scanned part will be covered with a grid that divides the space.
