Experiment Summary:

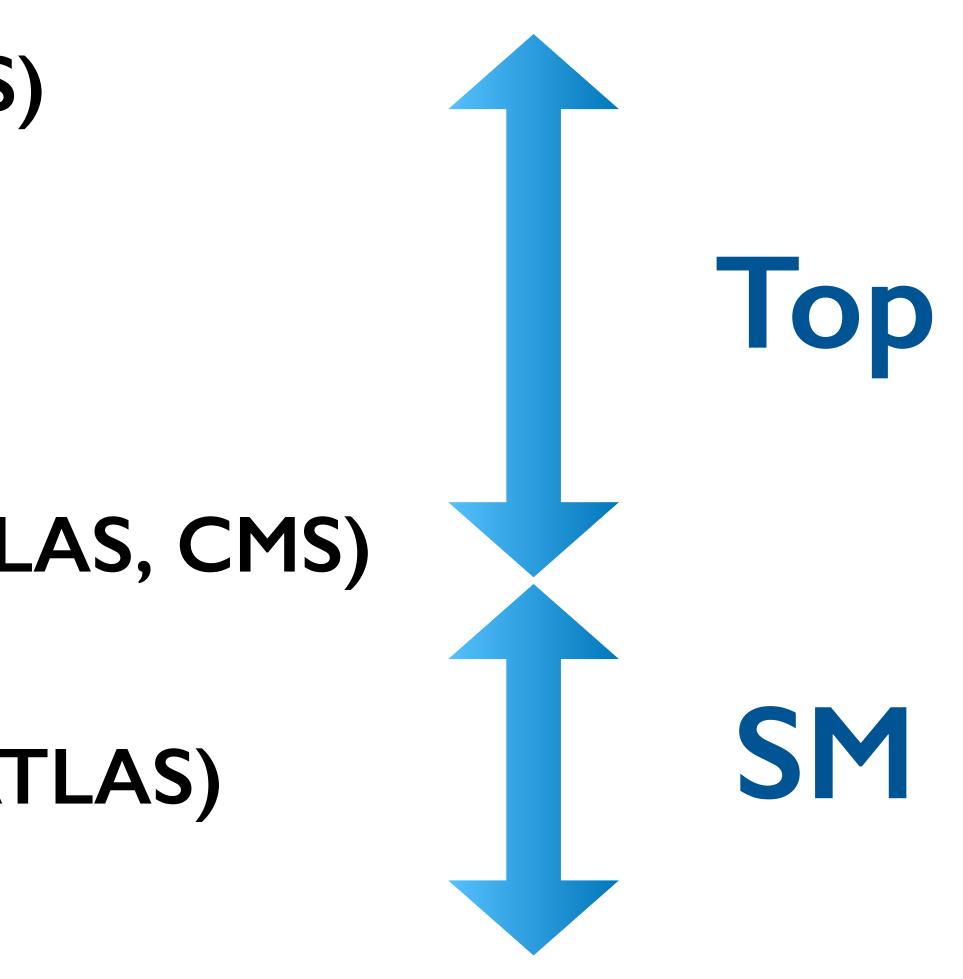

Yasuyuki Horii (Nagoya University)

Workshop for Tera-Scale Physics and Beyond, 23 Jun. 2023

Contents

- Top quark mass (ATLAS, CMS)
- o 4 top (ATLAS, CMS)
- o ttbb (CMS)
- o ttW (ATLAS)
- Run 3 top measurements (ATLAS, CMS)
- o W mass (ATLAS)
- $\circ a_s$ measurement from Z p_T (ATLAS)
- VBS (ATLAS, CMS)

Top Quark

- Special place in the SM:
 - Heaviest elementary particle
 - Connection to Electroweak
 Symmetry Breaking
 with large Yukawa coupling (λ~1)
- Unique quark:
 - Extremely short lifetime (T~10-25 s)
 - Decays before hadronisation
 - Allows to probe properties
 of bare quark
 - Almost exclusively to Wb

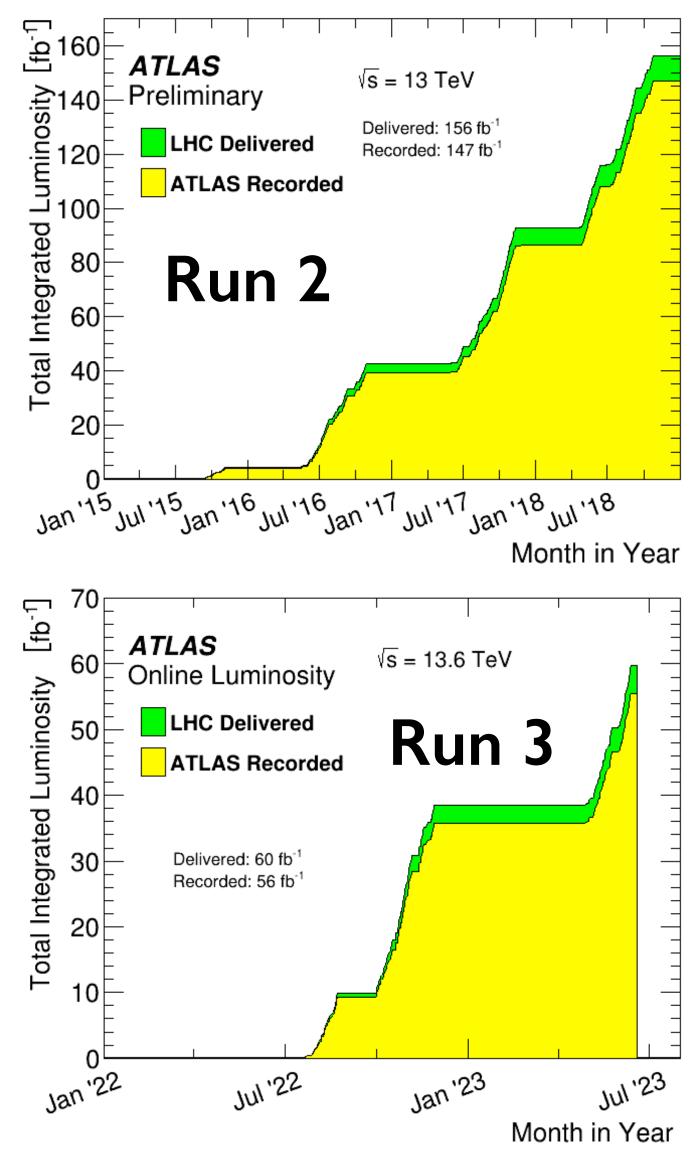

Top Precision Physics at the LHC

- LHC: top quark factory 0
 - ~ 20 million top quark pairs produced during Run 2 in each experiment
 - More to come in Run 3
- Allows for precision studies
 - Probe top quark properties, e.g. mass
 - Improve modelling understand and control uncertainties
- Also can search for **BSM** effects

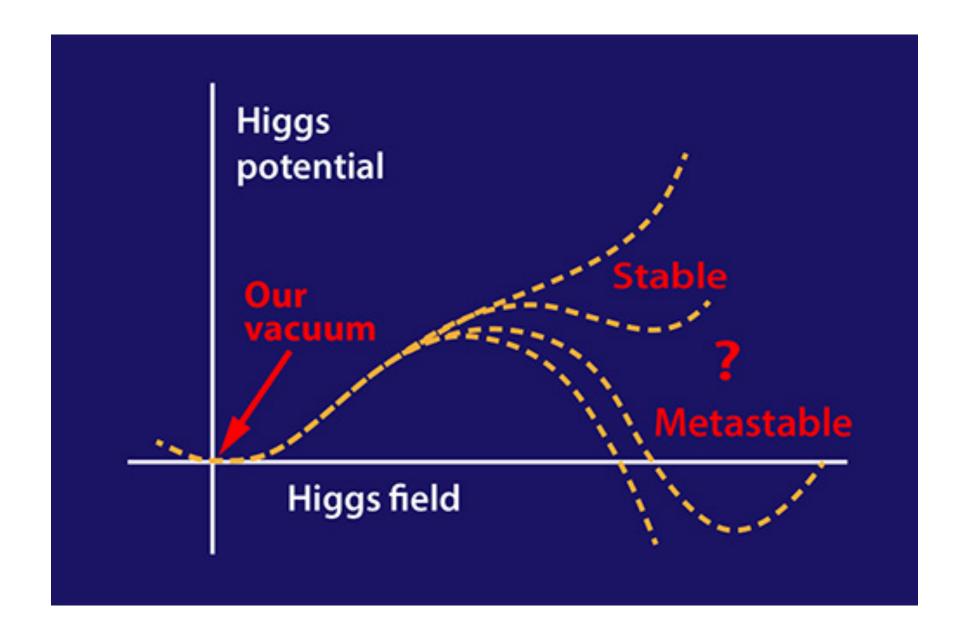

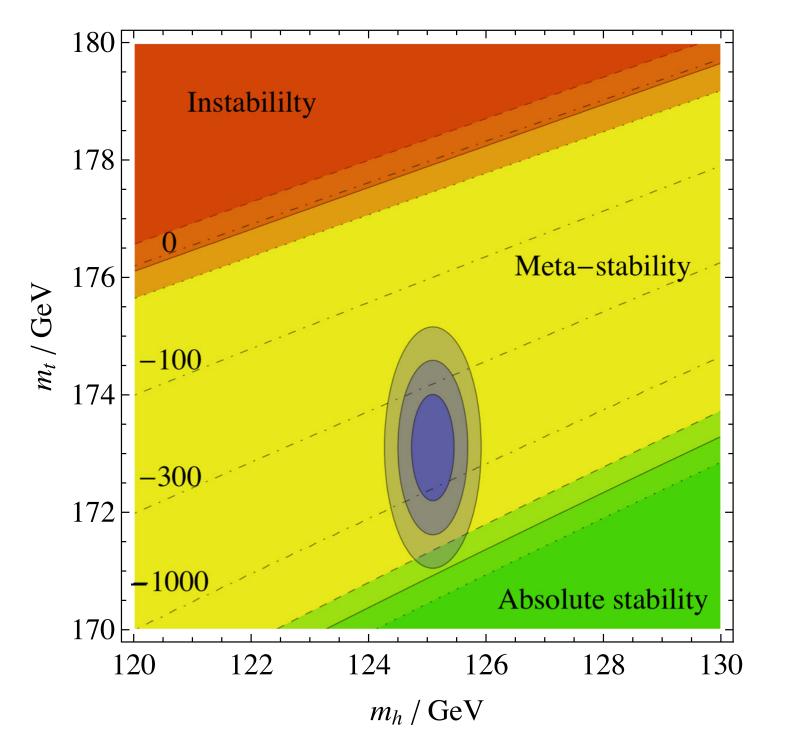

Top Quark Mass — Introduction

- Top quark mass (m_t) is a fundamental parameter of the SM Ο
- m_t , m_W and m_H measurements can be compared to EW fit predictions to check the validity of SM
- o mt is crucial for the stability of the electroweak vacuum in the SM

APS/Alan Stonebraker, https://physics.aps.org/articles/v8/108

 $m_h = 125.09 \pm 0.24,$ $m_t = 173.1 \pm 0.6$, $\alpha_s(m_Z) = 0.1181 \pm 0.0011,$

Meta-stability preferred(?)

S. Chigusa, T. Moroi, and Y. Shoji, Phys. Rev. D 97, 116012 (2018)

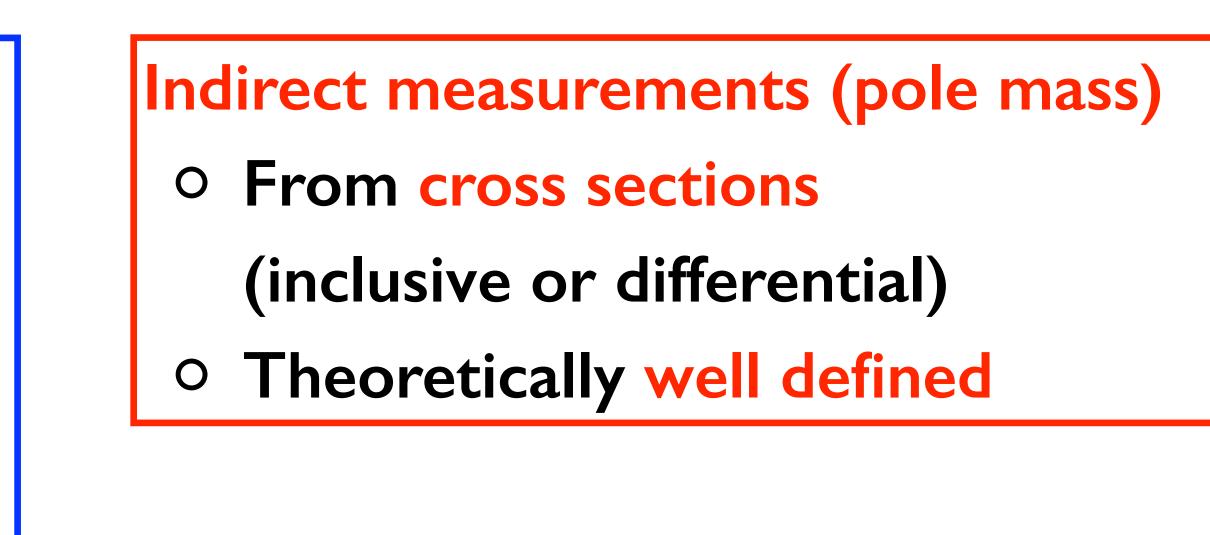

Top Quark Mass — Direct and Indirect Measurements

Direct measurements (MC mass) From full or partial kinematic Ο reconstruction of invariant mass of top decay products, comparison with MC calculations Theoretically not well defined

Relating the MC mass to a field theory mass is challenging because of hadronization and parton-shower dynamics, but the uncertainty reached a few hundred MeV.

PRL 117, 232001 (2016)

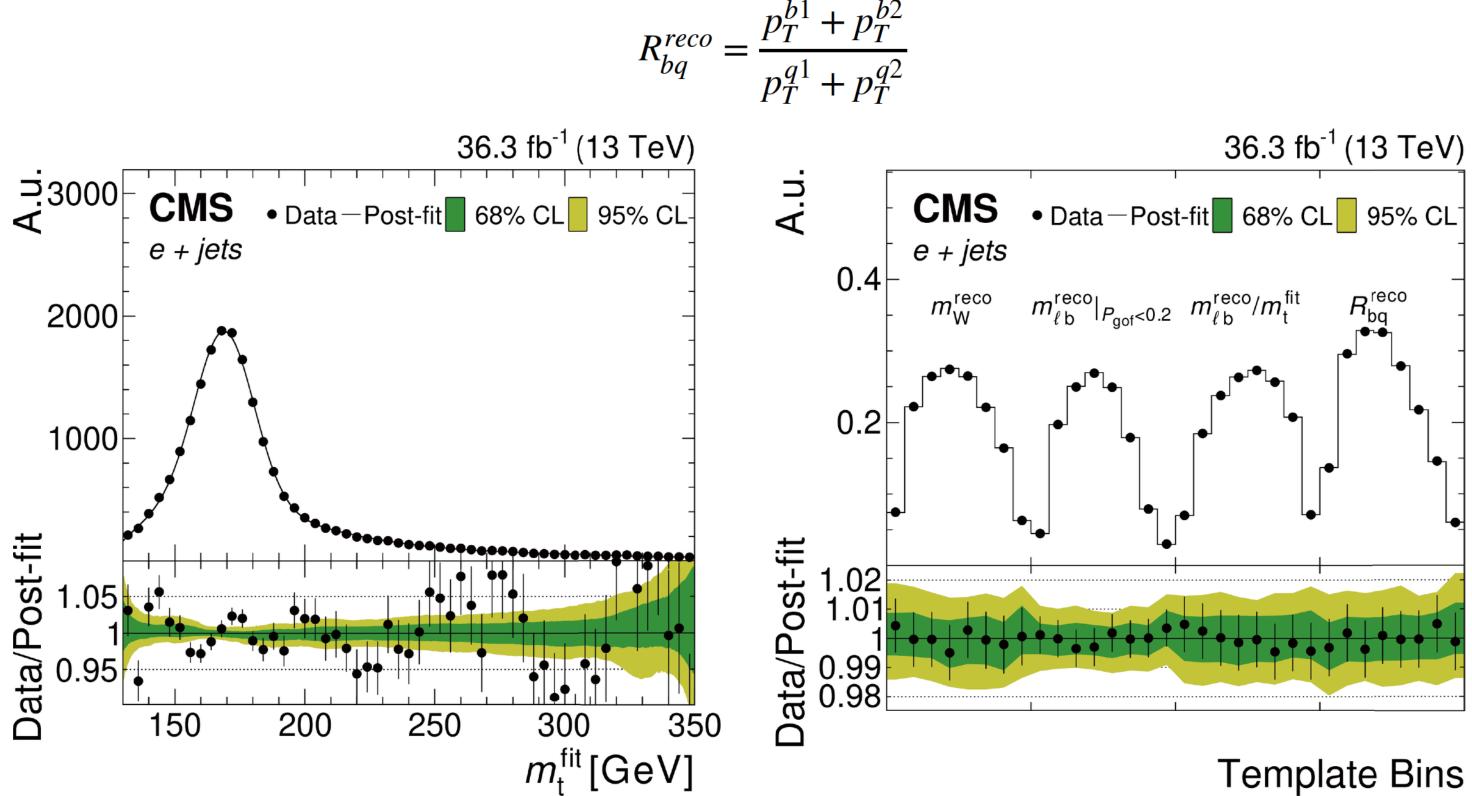

Top Quark Mass — Direct Measurement with I+jets

Unprecedented precision result by a fit of 5 observables • m_t^{fit} and $m_{\ell b}^{\text{reco}}$: sensitive to m_t o $m_{\rm W}^{\rm reco}$, $m_{\ell \rm b}^{\rm reco}/m_{\rm t}^{\rm fit}$, and $R_{ba}^{\rm reco}$: constraint of systematics

$$m_t^{\rm MC} = 171.77 \pm 0.37 ~\rm Ge$$

Recent results: relatively low mt Getting closer to the absolute stability?

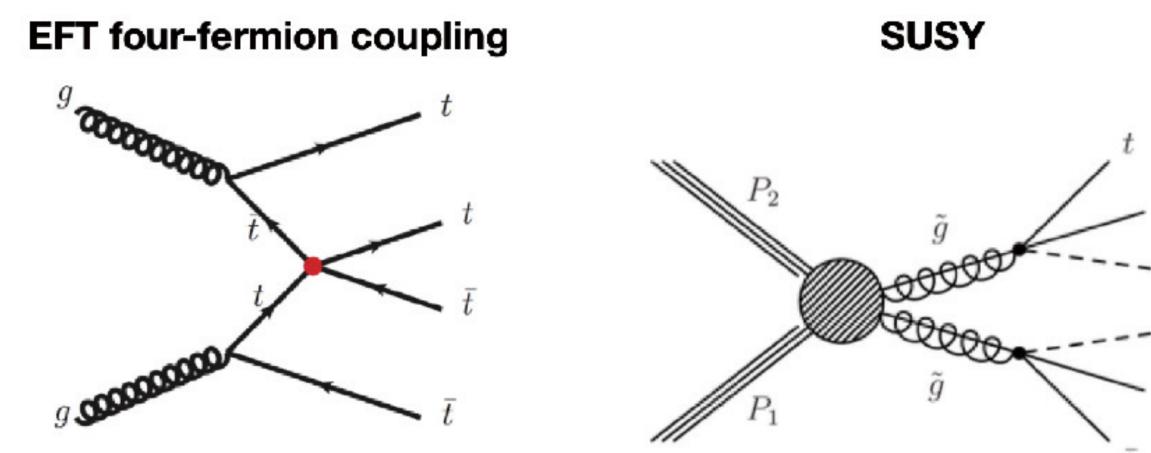

4 Top — Introduction

• Sensitive to top Yukawa coupling and potential BSM effects

• $\sigma_{t\bar{t}t\bar{t}} = 13.4^{+1.0}_{-1.8}$ fb (NLO (QCD + EW) + NLL @13TeV) [arXiv:2212.03259]

Small cross section — no observation in previous analyses

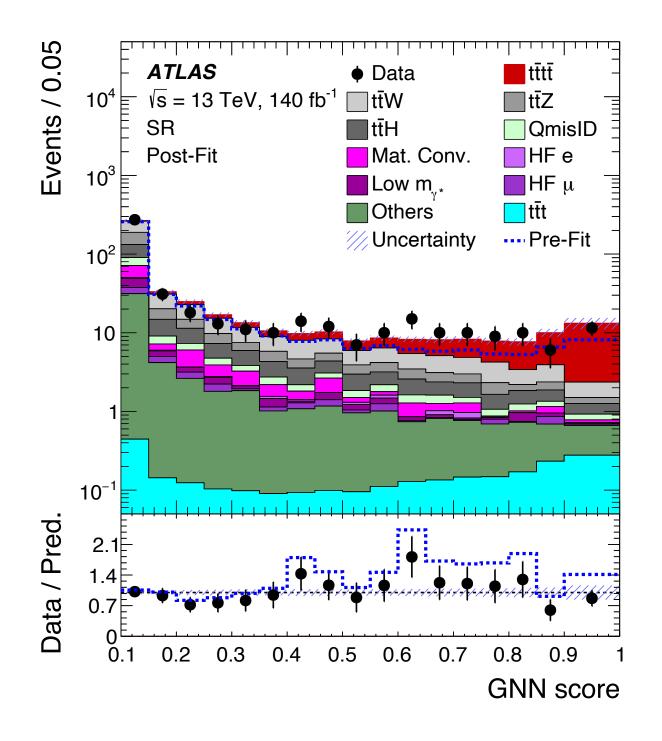

4 Top — First Observation

ATLAS [arXiv:2303.15061] Observed (expected): 6.1σ (4.3σ)

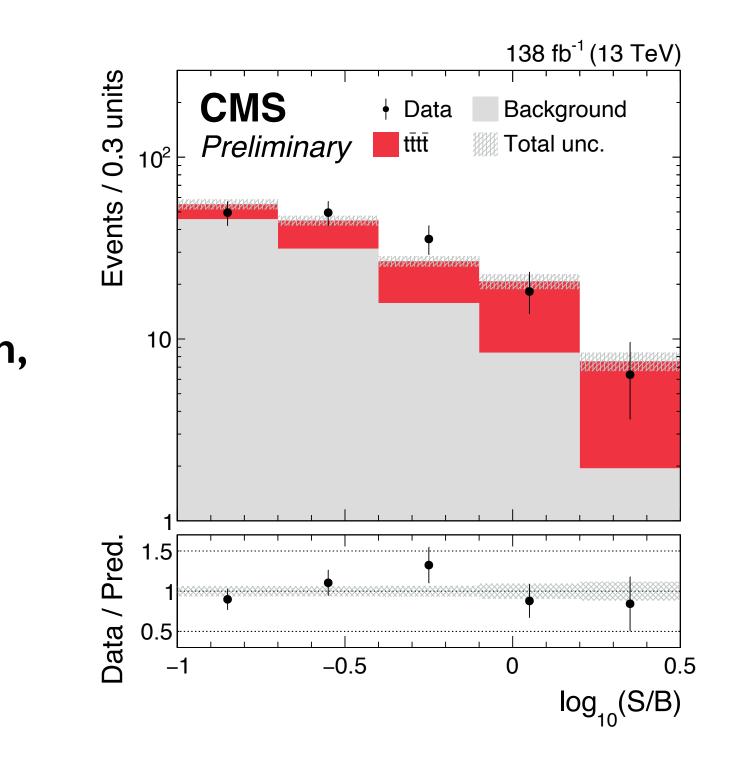

Looser event selection, improved ttW estimation, graph neural network with nodes: reco objects

 $\sigma_{t\bar{t}t\bar{t}} = 22.5^{+6.6}_{-5.5}$ fb

The measured cross section in agreement with the SM

CMS [<u>arXiv:2303.15061</u>] Observed (expected): 5.5σ (4.9 σ)

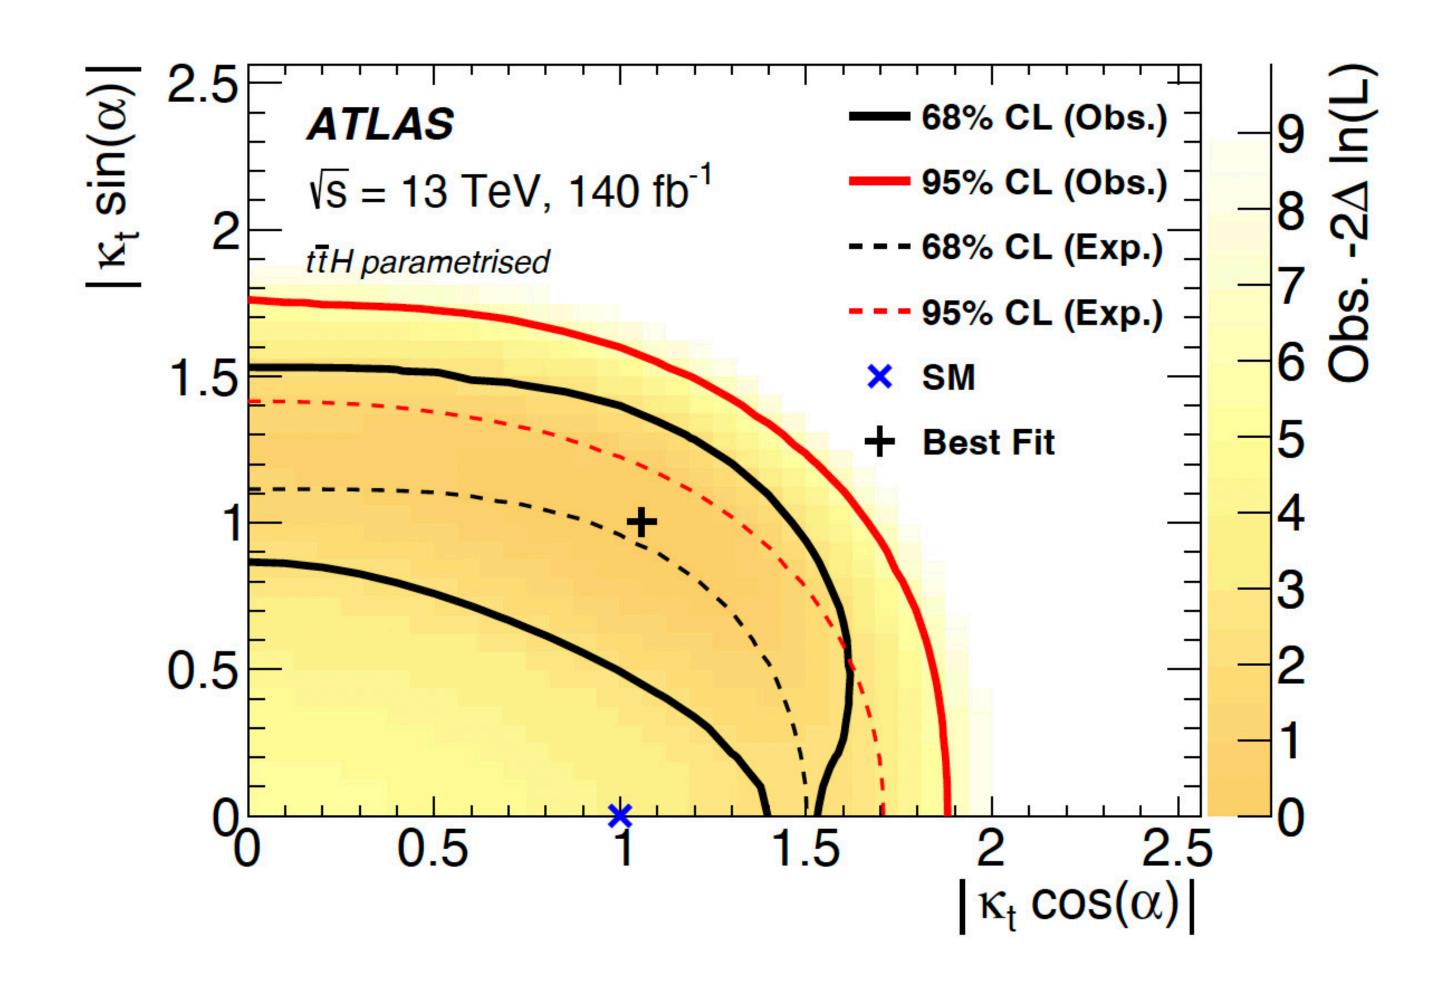

BDT lepton ID, multiclassification **BDT** for background separation

 $\sigma_{t\bar{t}t\bar{t}} = 17.9^{+3.7}_{-3.5}(\text{stat})^{+2.4}_{-2.1}(\text{syst}) \text{ fb}$

4 Top — Interpretation

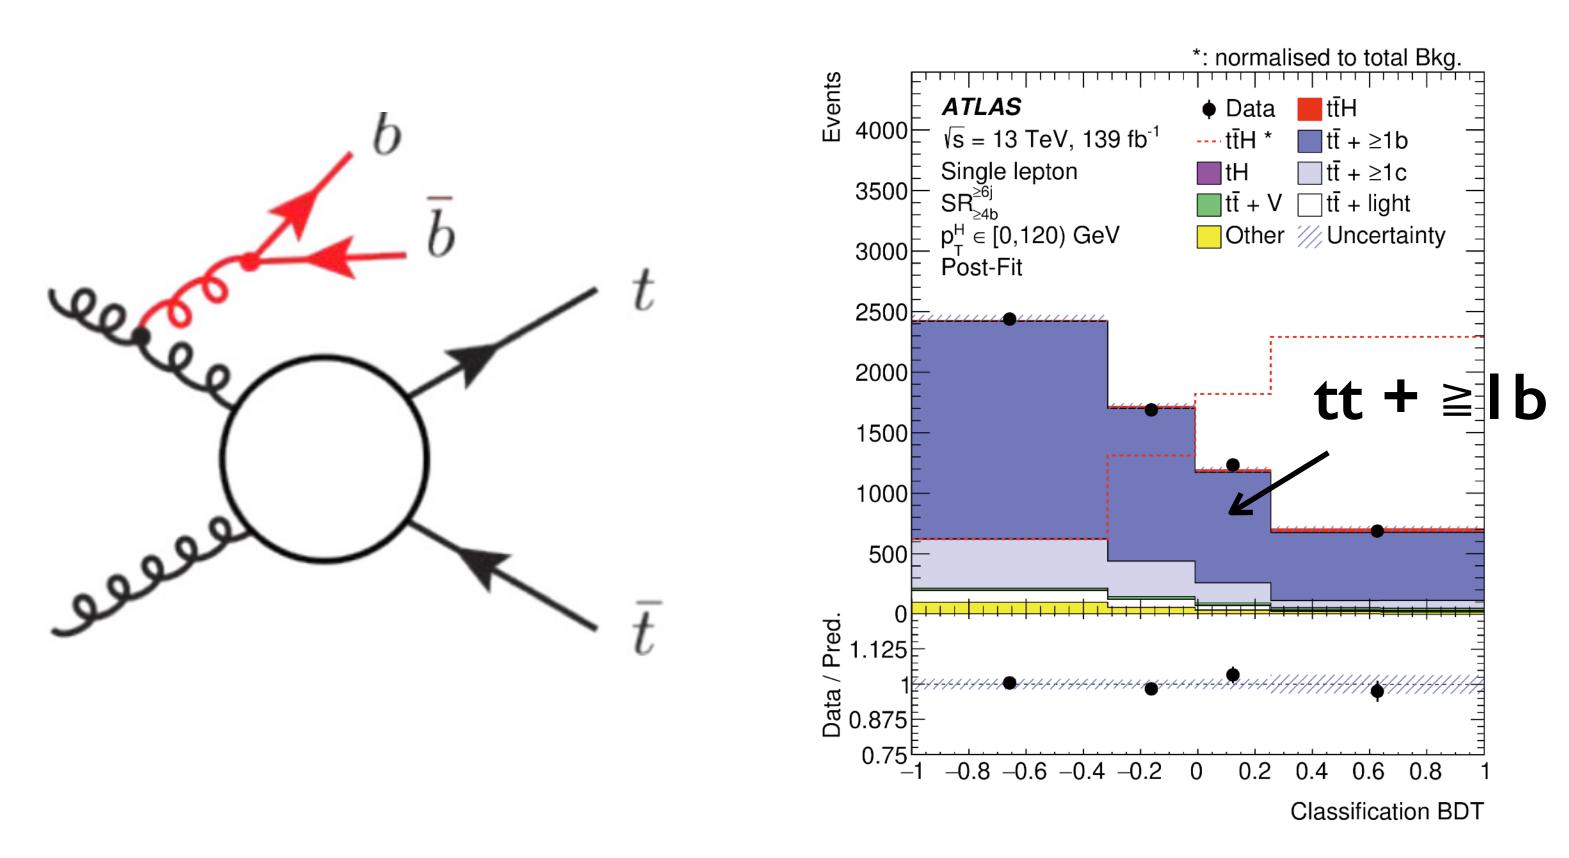

K_t: top-Higgs Yukawa coupling strength parameter

W Mass — Introduction

- In 2017, ATLAS published <u>the LHC's</u> first measurement of the W-boson mass: 80370 ± 19 MeV — the most precise single-experiment result, in agreement with the SM prediction and all other experimental results.
- Last year, the CDF Collaboration at Fermilab published an even more precise measurement of the W-boson mass: 80434 ± 9 MeV — deviated significantly from the SM prediction and from other experimental results.

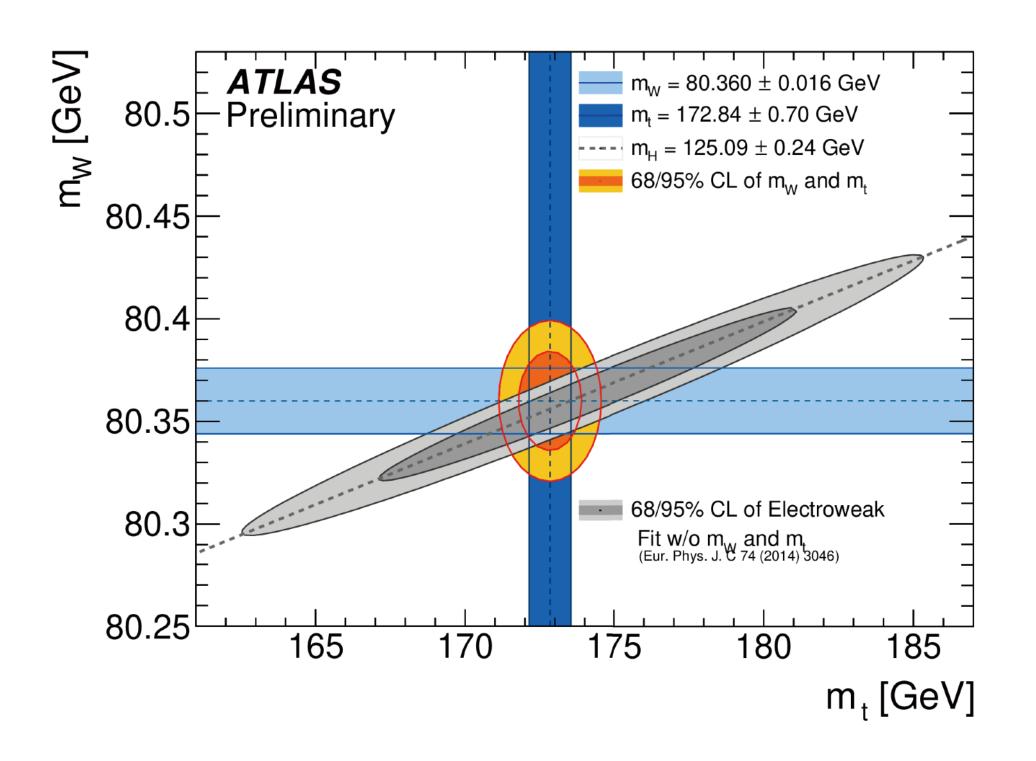

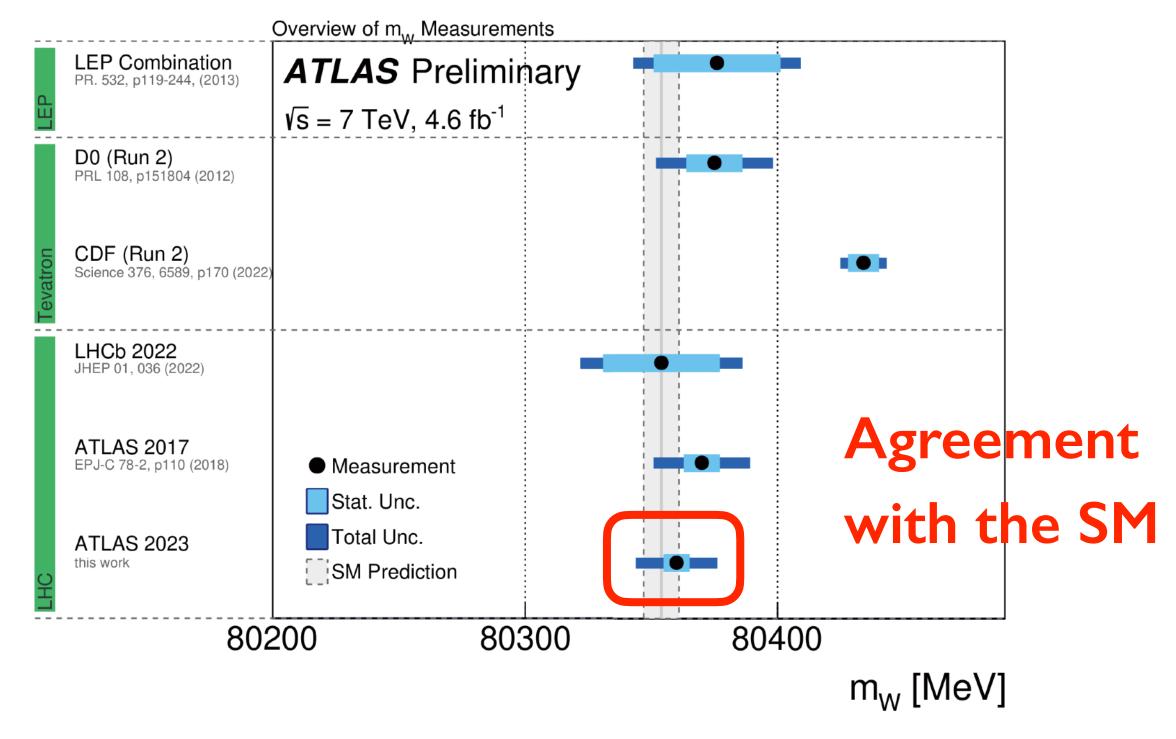

W Mass — Recent Result from ATLAS

Reanalysis of 7 TeV data — reduction of total uncertainty by 15 % by updated PDFs (CTI0NNLO \rightarrow CTI8NNLO), improvements in statistical analysis, ...

 $m_W = 80360 \pm 5(\text{stat.}) \pm 15(\text{syst.}) = 80360 \pm 16 \text{ MeV}$

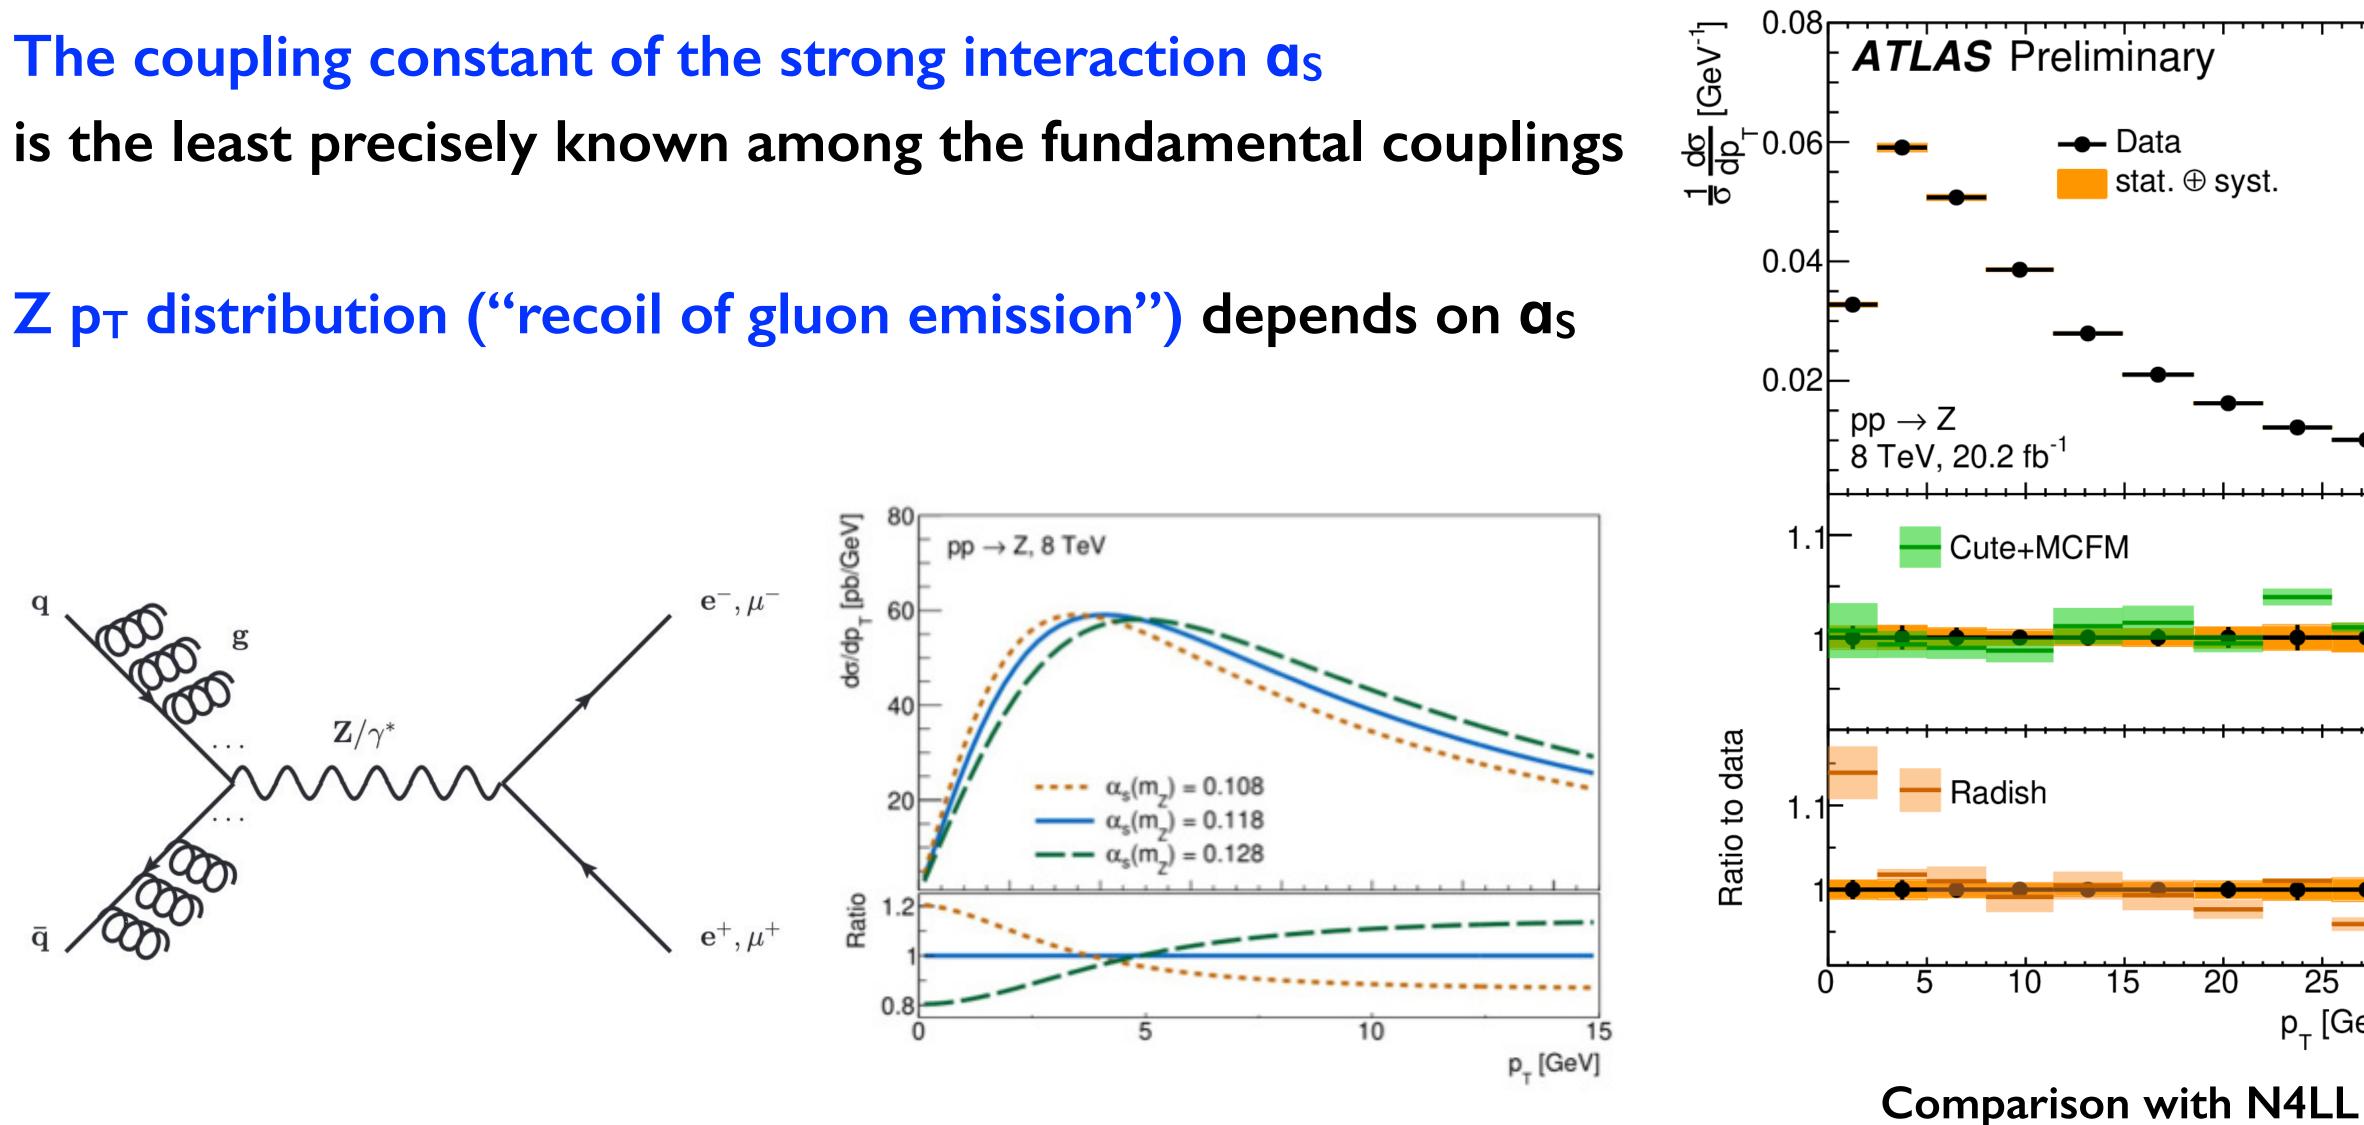

ATLAS-CONF-2023-004

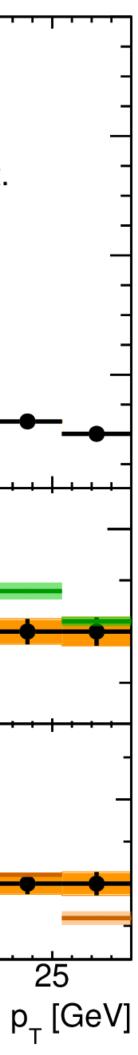

Awaiting a CMS result ...

ds Measurement from Z pt ATLAS-CONF-2023-013

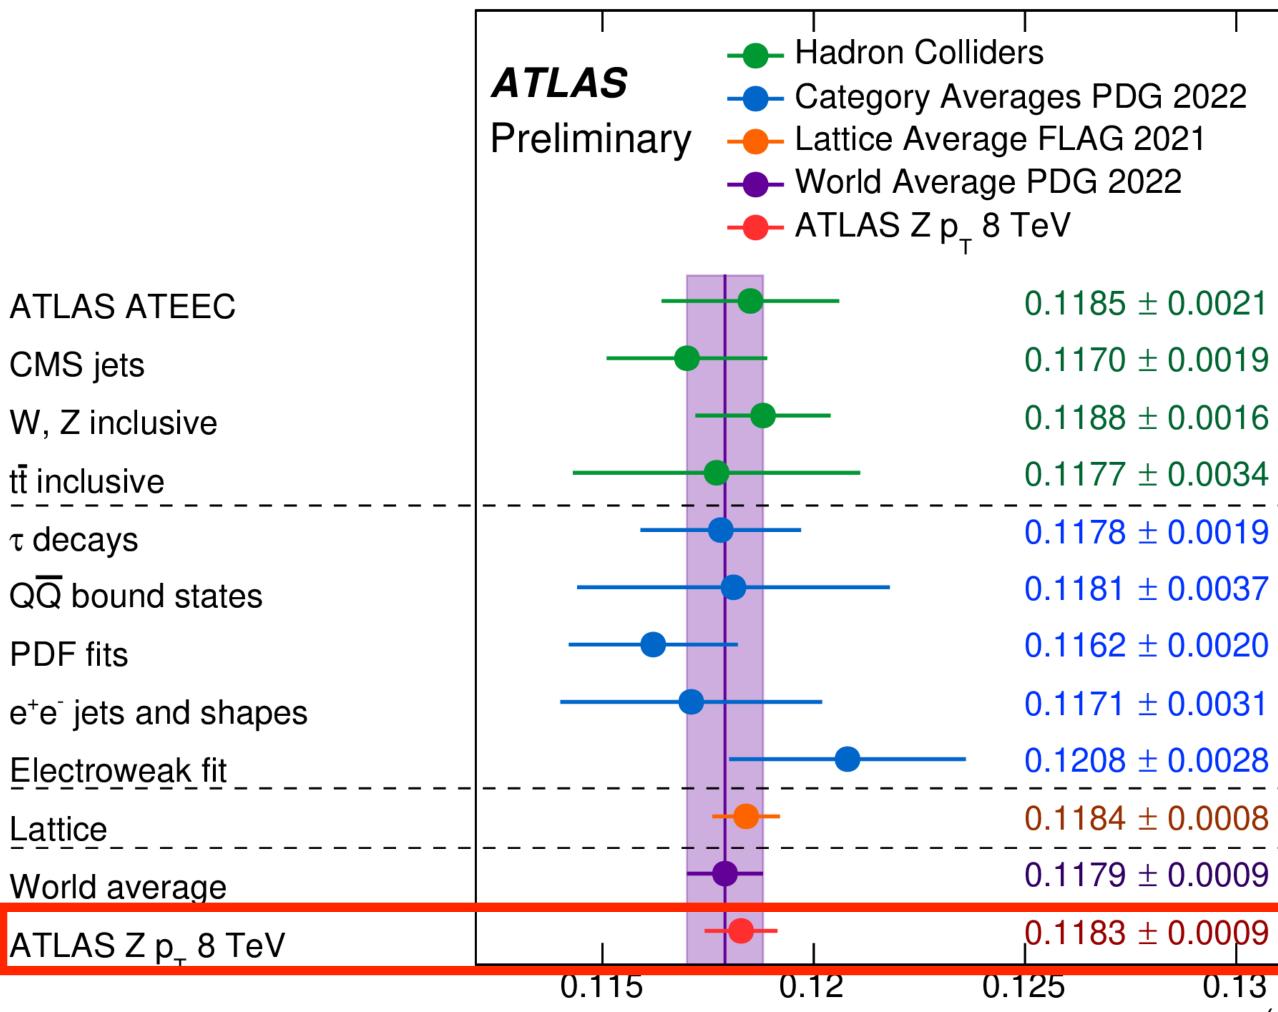

ds Measurement from Z pt

Most precise experimental measurement on \mathbf{a}_{S} , and first time using N3LO+N4LL $p_T(Z)$ predictions **Precision of a_s important to reduce** the associated theoretical uncertainty which enters into all cross-section calculations for processes at the LHC

ATLAS-CONF-2023-015

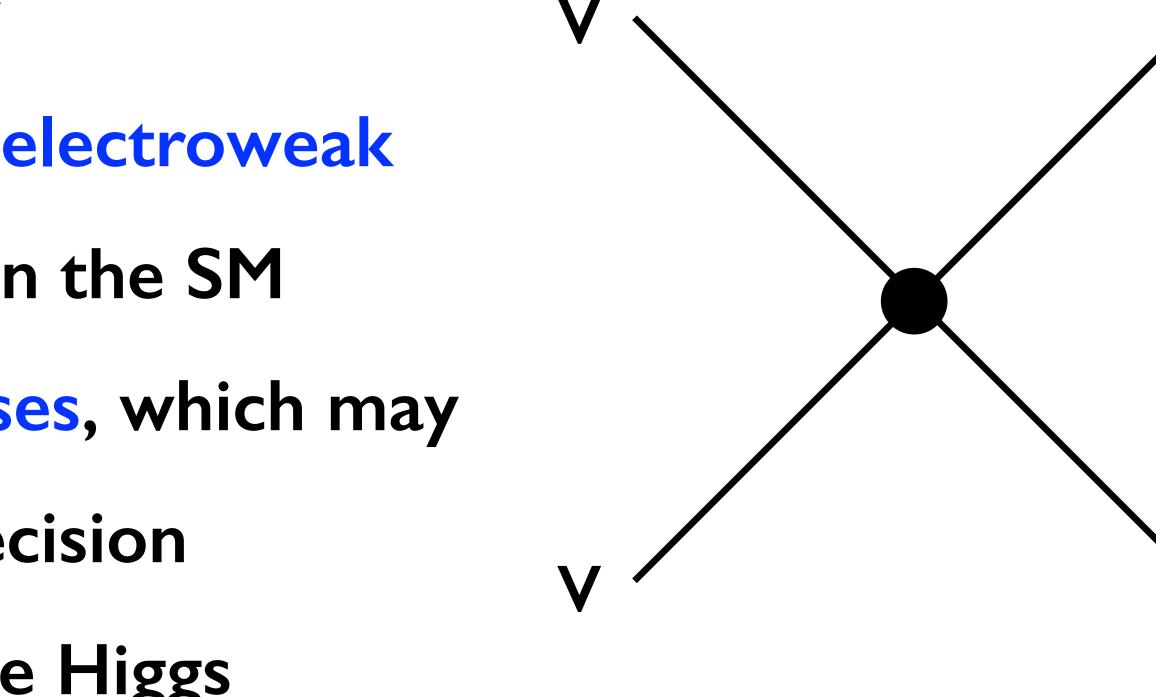

VBS — Introduction

- Vector boson scattering (VBS),
- $VV \rightarrow VV (V = W^{\pm}/Z/\gamma)$, is crucial for
- o understanding the nature of the electroweak symmetry-breaking mechanism in the SM
- searches for new physics processes, which may impact the scattering at high precision
- studies of the Higgs sector, as the Higgs mechanism impacts the scattering rate.

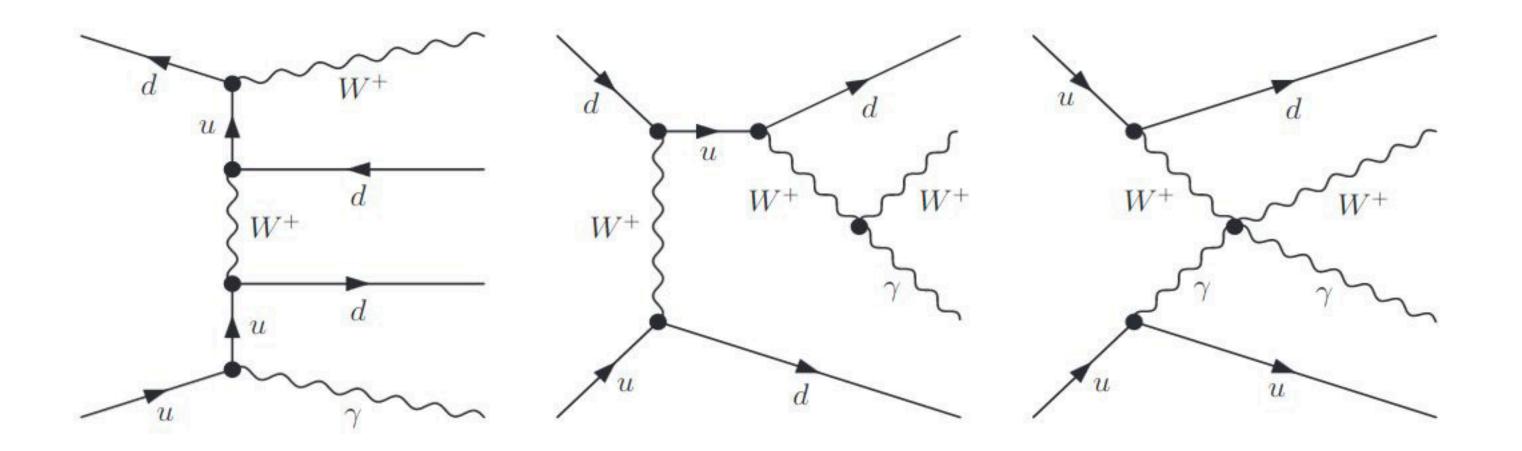

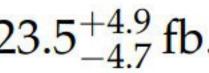

- Recent Results from CMS arXiv:2212.12592 VBS

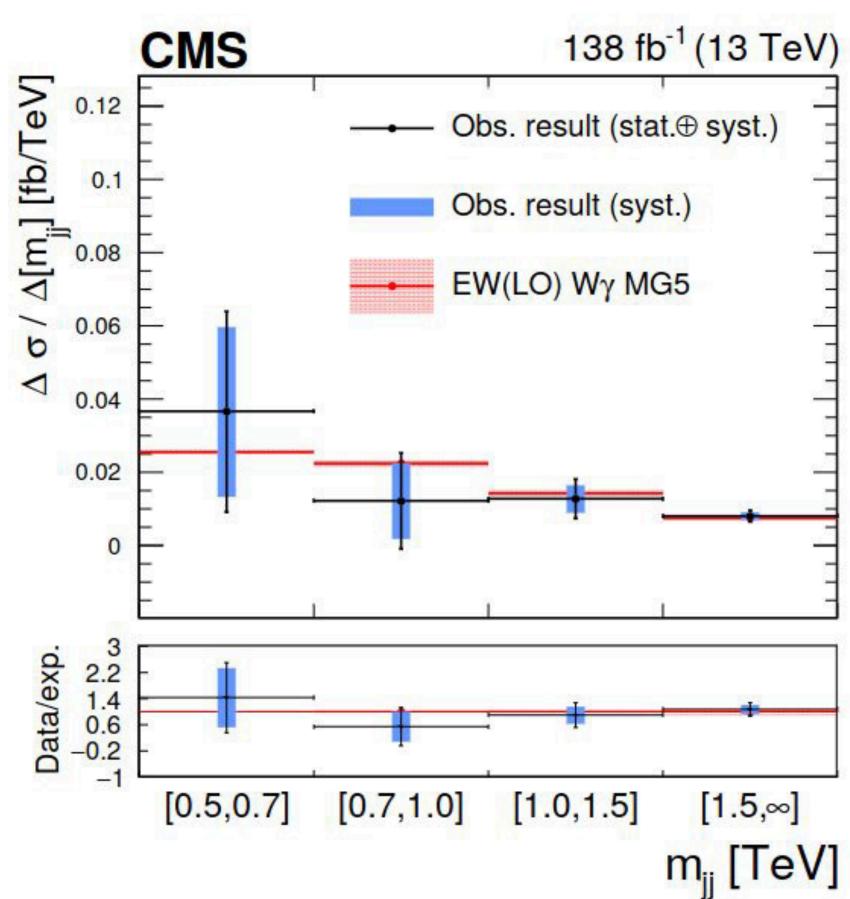

Wy: 6.0 (6.8) σ observed (expected)

 $\sigma_{\rm EW}^{\rm fid} = 23.5 \pm 2.8 \,({\rm stat})^{+1.9}_{-1.7} \,({\rm theo})^{+3.5}_{-3.4} \,({\rm syst}) \,{\rm fb} = 23.5^{+4.9}_{-4.7} \,{\rm fb}.$

Fiducial and differential cross sections measured Stringent limits on anomalous quartic gauge couplings

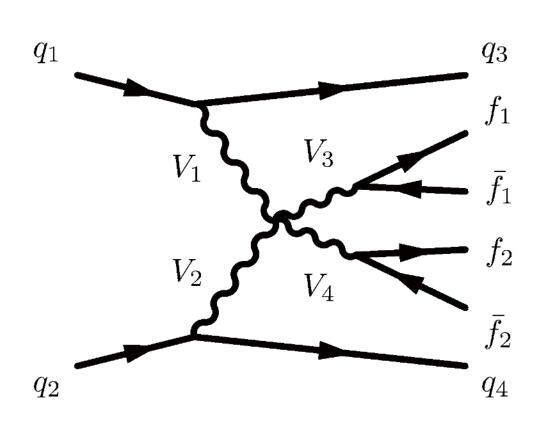

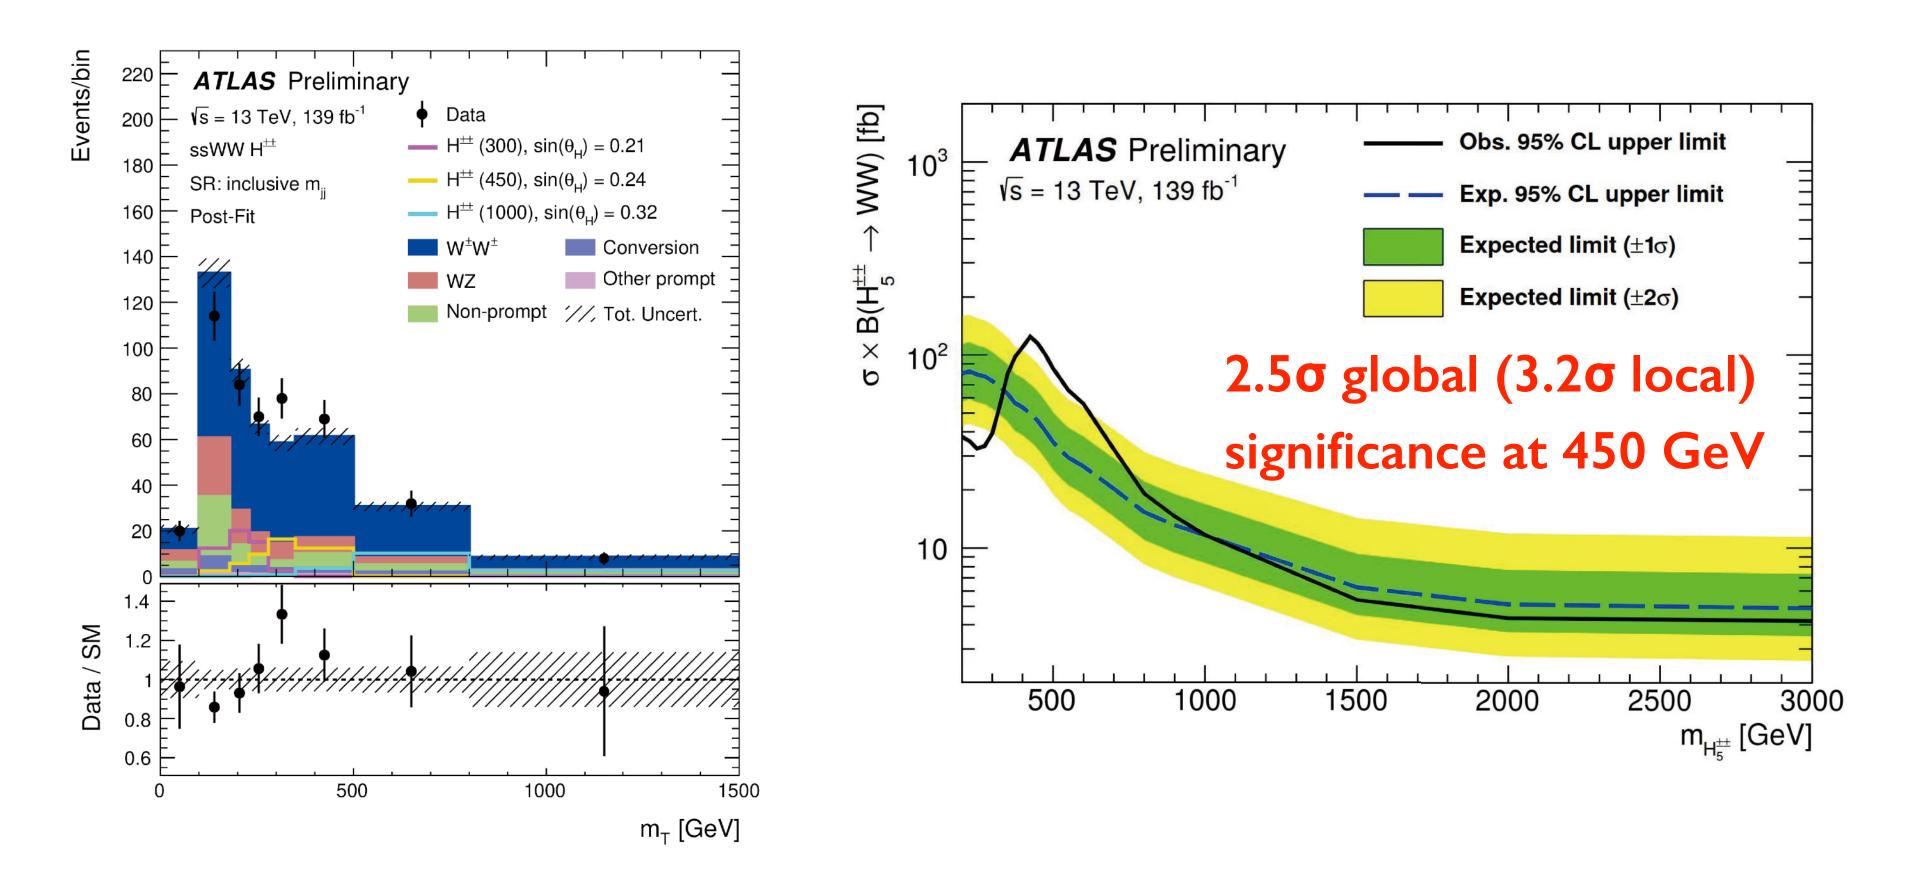

VBS — Recent Results from ATLAS

ATLAS showed new results on same-sign WW (below), ZZ (backup), and ZY (backup).

- Fiducial and differential cross sections measured

• Searches for anomalous quartic gauge couplings and doubly charged Higgs (e.g. in GM model)

Summary

- Top quark mass new era: 0.4 GeV precision by single measurement Electroweak vacuum: closer to absolute stability(?)
- First tttt observation: new probe of top Yukawa coupling and new physics
- New ttbb and ttW measurements (most precise and differential)
- First Run 3 measurements for top quark pair production
- ATLAS results on W mass consistent with the SM — no convincing explanations on the deviation for CDF II result
- Most precise experimental measurement on $\mathbf{Q}_{\mathbf{S}}$ using $\mathbf{Z} \mathbf{p}_{\mathbf{T}}$
- 2.5σ global (3.2σ local) significance at 450 GeV in same-sign WW

The Standard Model still reigns supreme! Stay tuned for Run 3 results!

PRD 97 (2018) 056006

Top Quark Mass — Direct Measurement with I+jets

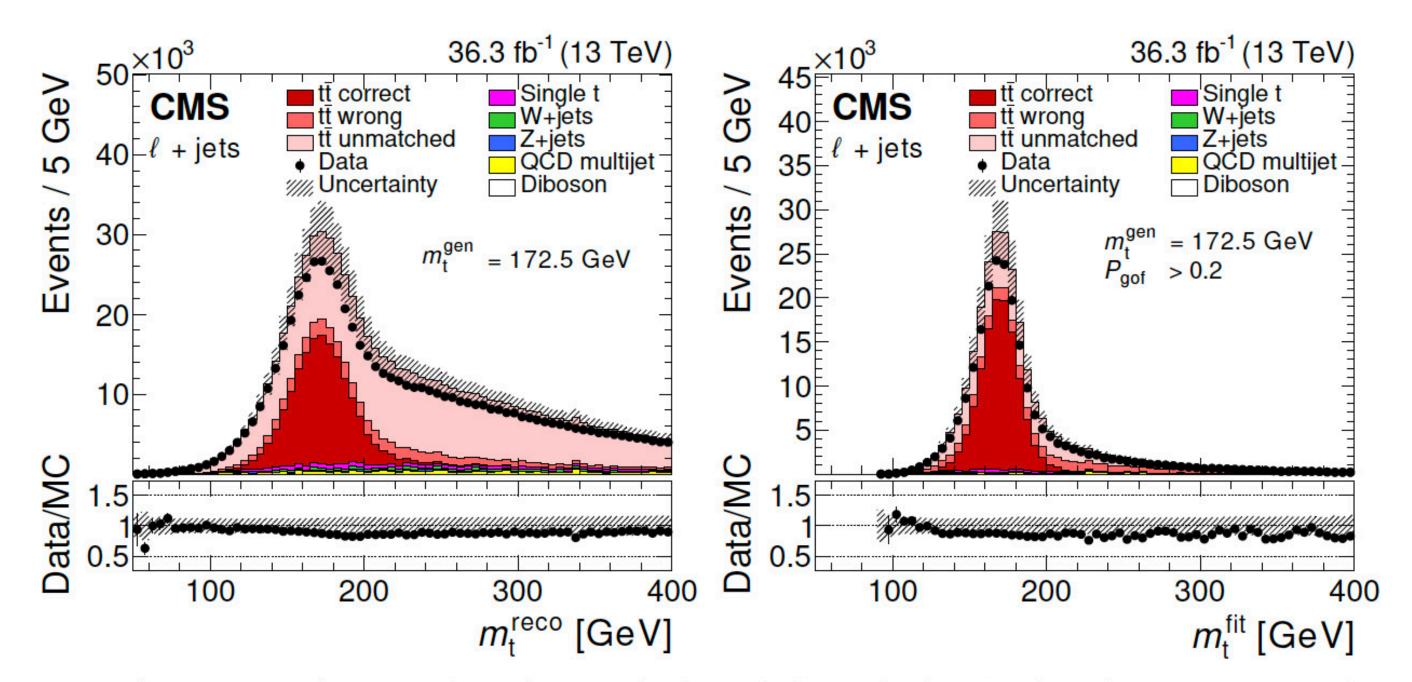

Figure 1: The top quark mass distribution before (left) and after (right) the $P_{gof} > 0.2$ selection and the kinematic fit. For the simulated $t\bar{t}$ events, the jet-parton assignments are classified as correct, wrong, and unmatched permutations, as described in the text. The uncertainty bands contain statistical uncertainties in the simulation, normalization uncertainties due to luminosity and cross section, jet energy correction uncertainties, and all uncertainties that are evaluated from event-based weights. A large part of the depicted uncertainties on the expected event yields are correlated. The lower panels show the ratio of data to the prediction. A value of $m_t^{\text{gen}} = 172.5 \,\text{GeV}$ is used in the simulation.

arXiv:2302.01967

mt^{fit}: the invariant mass for hadronically decaying top quark after kinematic fit and requirement on goodness-of-fit for parton-jet assignment.

The kinematic fit constrains 4-momenta to the hypothesis that two heavy particles of equal mass are produced, each one decaying to a b quark and a W boson, with the invariant mass of the latter constrained to 80.4 GeV.

Top Quark Mass — Direct Measurement with I+jets

For most tt events, a low P_{gof} value is caused by assigning a wrong jet to the W boson candidate, while the two btagged jets are the correct candidates for the b quarks. Hence, m_{lb}^{reco} preserves a good mt dependence and adds additional sensitivity to the measurement.

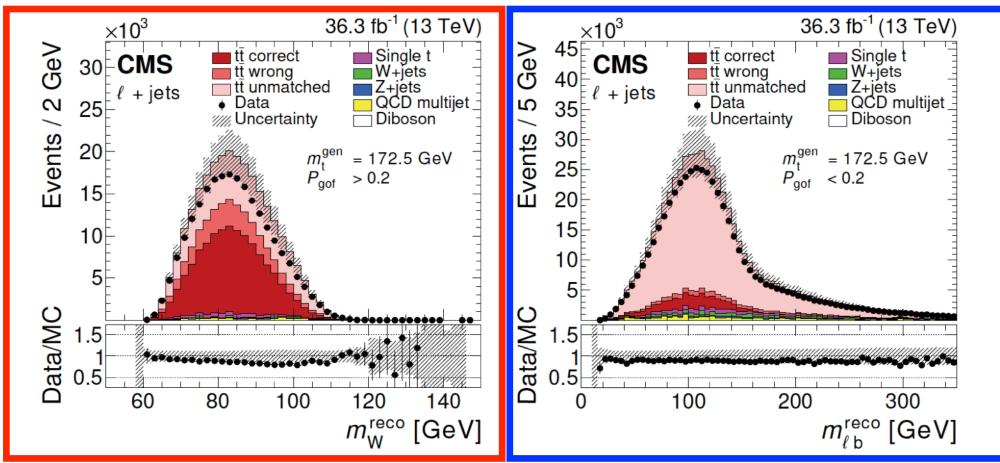

Figure 2: The distributions of the reconstructed W boson mass for the $P_{gof} > 0.2$ category (left) and of the invariant mass of the lepton and the jet assigned to the semileptonic decaying top quark for the $P_{gof} < 0.2$ category (right). The uncertainty bands contain statistical uncertainties in the simulation, normalization uncertainties due to luminosity and cross section, jet energy correction uncertainties, and all uncertainties that are evaluated from event-based weights. A large part of the depicted uncertainties on the expected event yields are correlated. The lower panels show the ratio of data to the prediction. A value of $m_t^{\text{gen}} = 172.5 \,\text{GeV}$ is used in the simulation.

Additional observables are used in parallel for the mass extraction to constrain systematic uncertainties. In previous analyses by the CMS Collaboration in the lepton+jets channel [11, 13], the invariant mass of the two untagged jets before the kinematic fit m_W^{reco} , has been used together with m_t^{fit} , mainly to reduce the uncertainty in the jet energy scale and the jet modeling. Its distribution is shown in Fig. 2 (left). As *m*_W^{reco} is only sensitive to the energy scale and modeling of light flavor jets, two additional observables are employed to improve sensitivity to the scale and modeling of jets originating from b quarks. These are the ratio $m_{\ell b}^{\rm reco}/m_t^{\rm fit}$, and the ratio of the scalar sum of the transverse momenta of the two b-tagged jets (b1, b2), and the two non-b-tagged jets (q1, q2), $R_{bq}^{reco} = (p_T^{b1} + p_T^{b2})/(p_T^{q1} + p_T^{q2})$. Their distributions are shown in Fig. 3. While m_t^{fit} and m_W^{reco} have been used by the CMS Collaboration in previous analyses in the lepton+jets channel, $m_{\ell b}^{\text{reco}}$, $m_{\ell b}^{\text{reco}}/m_t^{\text{fit}}$, and R_{bq}^{reco} are new additions. However, R_{bq}^{reco} has been used in the lepton+jets channel by the ATLAS Collaboration [10, 53].

<u>arXiv:2302.01967</u>

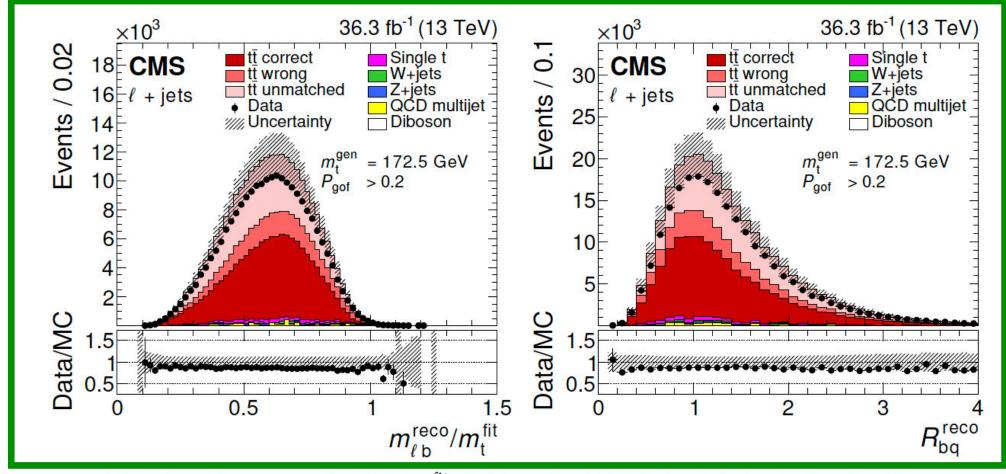

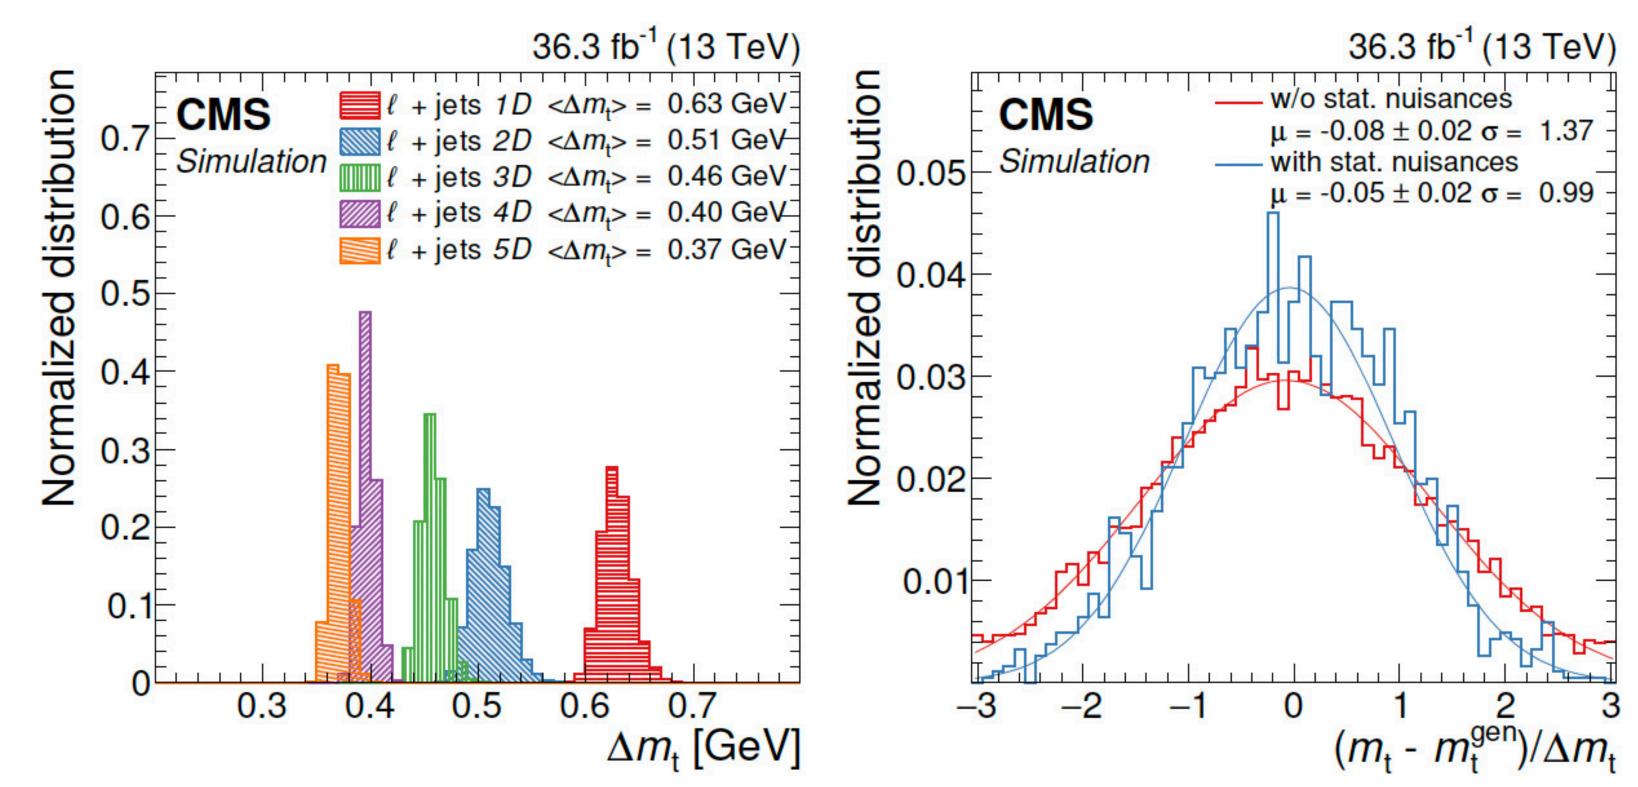

Figure 3: The distributions of $m_{\ell b}^{\text{reco}}/m_t^{\text{fit}}$ (left) and of R_{bq}^{reco} (right), both for the $P_{\text{gof}} > 0.2$ category. The uncertainty bands contain statistical uncertainties in the simulation, normalization uncertainties due to luminosity and cross section, jet energy correction uncertainties, and all uncertainties that are evaluated from event-based weights. A large part of the depicted uncertainties on the expected event yields are correlated. The lower panels show the ratio of data to the prediction. A value of $m_t^{\text{gen}} = 172.5 \text{ GeV}$ is used in the simulation.

Top Quark Mass — Direct Measurement with I+jets

functions (red and blue lines) fit to the histograms.

Figure 4: Left: Comparison of the expected total uncertainty in m_t in the combined lepton+jets channel and for the different observable-category sets defined in Table 1. Right: The difference between the measured and generated m_t values, divided by the uncertainty reported by the fit from pseudo-experiments without (red) or with (blue) the statistical nuisance parameters $\vec{\beta}$ and $\vec{\omega}$ in the 5D ML fit. Also included in the legend are the μ and σ parameters of Gaussian

Top Quark Mass — "Recoil" Uncertainty

Gluon recoil schema in Phytia 8

arXiv:2209.00583

In the modelling of the parton shower of the b-quark from $t \rightarrow Wb$ with PYTHIA 8.2, there is the possibility to change the default gluon recoil scheme from recoiling against the *b*-quark (the nominal setting, referred to here as RTB), to recoiling against the W-boson (RECOILTOCOLOURED=OFF, referred to as RTW) [103]. Before PYTHIA version 8.160, the RTW was the only possibility, but it could give unphysical radiation patterns and it is now kept as an option to understand the effect this setting has in view of previous measurements. This setting changes the modelling of second and subsequent gluon emission from quarks produced by coloured resonance decays, such as the b-quark in a $t \rightarrow Wb$ process, but it has no impact for example on $Z \rightarrow b\bar{b}$ decays. A third recoil scheme has been recently made available via the USERHOOK

Top Quark Mass — Projections

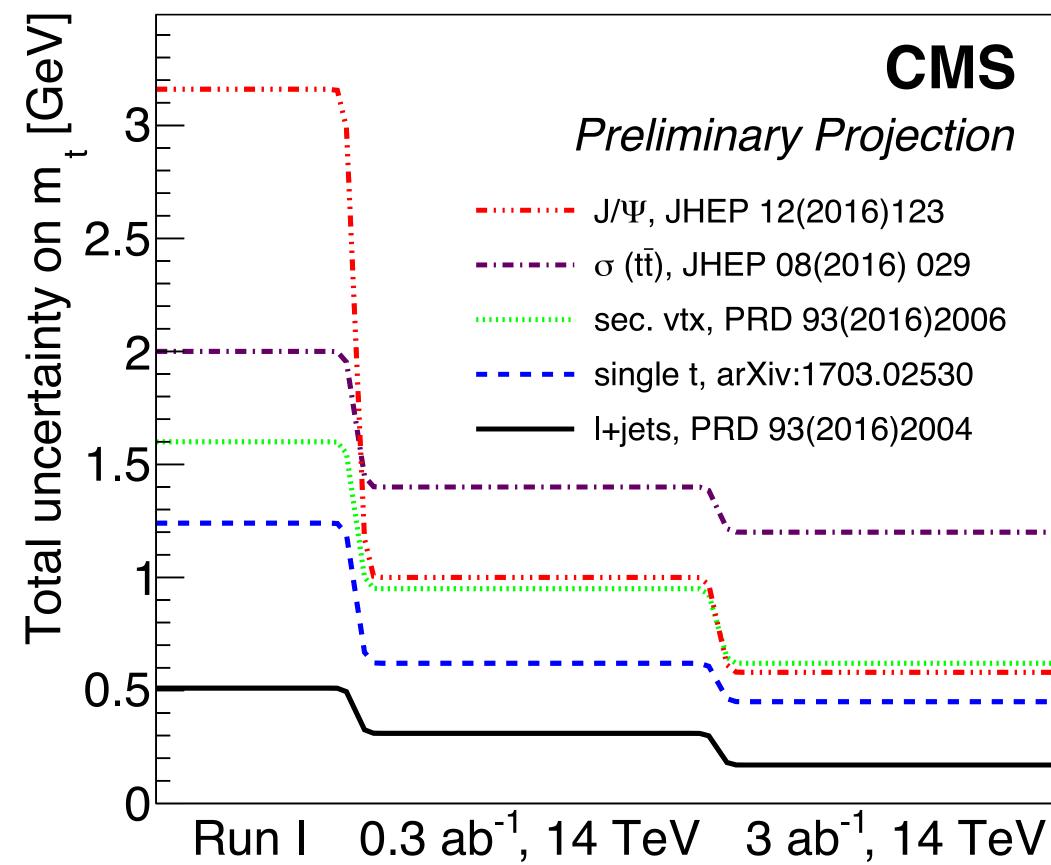

Figure 1: Total uncertainty on top quark mass (m_t) obtained with different measurement methods and their projections to the HL-LHC for running conditions foreseen after the phase II upgrade. The projections for $\sqrt{s} = 14$ TeV, with 0.3 ab⁻¹ or 3 ab⁻¹ of data, are based on m_t measurements performed at the LHC Run-1, assuming that an upgraded detector will maintain the same physics performance despite a severe pileup.

4 Top — Improvements in the Re-Analyses

<u>arXiv:2303.15061 (ATLAS)</u>

This paper presents a re-analysis of the 140 fb⁻¹ data set at $\sqrt{s} = 13$ TeV in the 2LSS/3L channel with the ATLAS detector and supersedes the result of Ref. [17]. Compared to the previous result that showed evidence for $t\bar{t}t\bar{t}$ production [17], this new measurement brings several improvements: an optimised selection with lower cuts on the leptons' and jets' transverse momenta; improved b-jet identification; a new data-driven estimation of the $t\bar{t}W$ +jets background, one of the main backgrounds in this channel; a revised set of systematic uncertainties; an improved treatment of the *tt* background and a more powerful multivariate discriminant to separate the signal from background. This paper also describes several

<u>arXiv:2303.15061 (CMS)</u>

from the same data set and found 2.6 (2.7) s.d. of observed (expected) significance. Notable discrimination between signal and background processes. The tttt production cross section $\sigma(pp \rightarrow t\bar{t}t\bar{t})$ is extracted with a profile likelihood fit to optimized distributions that provide good signal-to-background discrimination.

improvements include the use of state-of-the-art machine learning techniques in the lepton identification, in the tagging of jets originating from the hadronization of a b quark, and in the

Table 3: Summary of the sources of systematic uncertainty for $t\bar{t}$ + jets modelling. The systematic uncertainties listed in the second section of the table are evaluated in such a way as to have no impact on the normalisation of the three $t\bar{t} + \ge 1b$, $t\bar{t} + \ge 1c$, and $t\bar{t} + \text{light components in the phase-space selected in this analysis. The last column of the$ table indicates the $t\bar{t}$ + jets components to which a systematic uncertainty is assigned. All systematic uncertainty sources are treated as uncorrelated across the three components.
