

Cluster counting with IDEA drift chamber

Nicola De Filippis

Politecnico and INFN Bari
on behalf of the **DCH community**

ECFA Higgs Factories: 2nd Topical Meeting on Reconstruction

CERN, July 11-12, 2023

The IDEA detector at e^+e^- colliders

Innovative Detector for E+e- Accelerator

IDEA consists of:

- a silicon pixel vertex detector
- a large-volume extremely-light **drift chamber**
- surrounded by a layer of silicon micro-strip detectors
- a thin low-mass superconducting solenoid coil
- a preshower detector based on **μ -WELL technology**
- a dual read-out calorimeter
- muon chambers inside the magnet return yoke, based on **μ -WELL technology**

Low field detector solenoid to maximize luminosity (to contain the vertical emittance at Z pole).

→ optimized at 2 T

→ large tracking radius needed to recover momentum resolution

The Drift Chamber

The DCH is:

- a unique-volume, high granularity, fully stereo, low-mass cylindrical
- **gas:** He 90% - iC_4H_{10} 10%
- **inner radius** $R_{in} = 0.35m$, **outer radius** $R_{out} = 2m$
- **length** $L = 4m$
- **drift length** $\sim 1\text{ cm}$
- **drift time** $\sim 150ns$
- $\sigma_{xy} < 100\ \mu m$, $\sigma_z < 1\text{ mm}$
- **12÷14.5 mm wide square cells**, **5 : 1 field to sense wires ratio**
- **112 co-axial layers**, at alternating-sign stereo angles, arranged in 24 identical azimuthal sectors, with frontend electronics
- **343968 wires in total:**
 - sense wires:** 20 μm diameter W(Au) \Rightarrow 56448 wires
 - field wires:** 40 μm diameter Al(Ag) \Rightarrow 229056 wires
 - f. and g. wires:** 50 μm diameter Al(Ag) \Rightarrow 58464 wires
- the wire net created by the combination of + and - orientation generates **a more uniform equipotential surface** \rightarrow better E-field isotropy and smaller ExB asymmetries)
- a large number of wires requires a **non standard wiring procedure** and needs a **feed-through-less wiring system** \rightarrow a novel wiring procedure developed for the construction of the ultra-light MEG-II drift chamber

The Drift Chamber: Cluster Counting/Timing and PID

- **Analytic calculations:** Expected excellent K/π separation over the entire range except $0.85 < p < 1.05$ GeV (blue lines)
- **Simulation with Garfield++ and with the Garfield model ported in GEANT4:**
 - the particle separation, both with dE/dx and with dN_{cl}/dx , in GEANT4 found considerably **worse** than in Garfield
 - the dN_{cl}/dx Fermi plateau with respect to dE/dx is reached at **lower values of $\beta\gamma$ with a steeper slope**
 - finding answers by using real data from **beam tests at CERN in 2021, 2022 and 2023**

Cluster counting method:

- collect signal and identify peaks
- record the time of arrival of electrons generated in every ionisation cluster
- reconstruct the trajectory at the most likely position

Beam tests in 2021, 2022 and 2023

Beam tests to experimentally assess and optimize the **performance of the cluster counting/timing** techniques in strict collaboration with the IHEP Beijing group:

- two muon beam tests performed at CERN-H8 ($\beta\gamma > 400$) in Nov. 2021 and July 2022.
- a **muon beam test** in 2023 on going at **CERN**.
- ultimate test at **FNAL-MT6** in 2024 with π and **K** ($\beta\gamma = 10-140$) to fully exploit the relativistic rise.

Beam test setup at H8/CERN in 2021

11 drift tubes with different cell size and different material wires and diameter wires

The setup consisted of:

- 6 drift tubes 1 cm × 1 cm × 30 cm
 - 1 with 10 μm sense wire, 1 with 15 μm, 2 with 20 μm, 2 with 25 μm
- 3 drift tubes 2 cm × 2 cm × 30 cm
 - 1 with 20 μm sense wire, 1 with 25 μm, 1 with 40 μm
- 2 drift tubes 3 cm × 3 cm × 30 cm
 - 1 with 20 μm sense wire, 1 with 40 μm
- DRS board for data acquisition
- Gas mixing, control and distribution (only He and iC_4H_{10})
- 2 trigger scintillators

Helium used because of:

- Low primary ionization density implies a large time separation
- low drift velocity means larger time separation ($v_{\text{drift}} \approx 2.5 \text{ cm}/\mu\text{s}$)
- low average cluster size $\langle N_{\text{electrons}}/\text{cluster} \rangle \approx 1.6$
- low single electron diffusion ($< 110 \mu\text{m}$ for 0.5 cm drift, or $< 4.5 \text{ ns}$)

Beam test setup at H8/CERN in 2022

- 20 tubes with different wires (different material and diameter) and different cell size.
- 1 16-channel DRS
- 3 4-channel DRS
- the portable gas system
- custom PCBs for the 2 trigger scintillators.
- two external hard disk to store the data collected

- Data collected at different percentages of helium and isobutane: 90-10. , 85-15, 80-20.
- Data collected with muon beam with 180, 80 and 40 GeV momentum

NEW CONNECTION SCHEME

- Connect the 2 trigger scintillators to a 4-channels DRS
- Propagate the trigger signal to the 4-channel DRS and 16-channel DRS, where the tube are connected.

Data analysis in progress

Beam test setup at T10/CERN in 2023

- 20 tubes with different wires (different material and diameter) and different cell size.
- 1 16-channel DRS
- 2 4-channel DRS
- custom PCBs for the 2 trigger scintillators.
- two external hard disk to store the data collected

- Data to be collected at different percentages of helium and isobutane: 90-10. , 85-15, 80-20.
- Data to be collected with muon beam momentum between **1 and 12 GeV**

2021/2022 testbeam: find electron peaks algorithms

Find good electron peak candidates at position bin n and amplitude A_n :

FIRST AND SECOND DERIVATIVE (DERIV) ALGORITHM

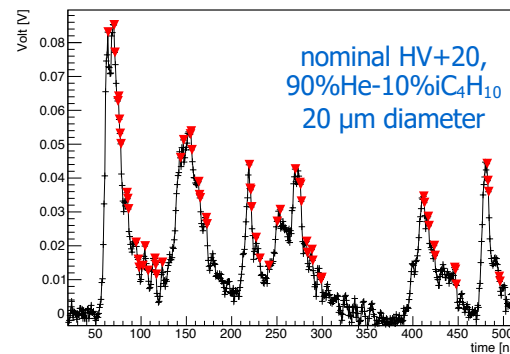

- ◆ Compute the first and second derivative from the amplitude average over two consecutive bins (1.6 ns for 1.2 GSa/s) and require that, at the peak candidate position, they are smaller than a r.m.s. signal-related small quantity and they increase (decrease) before (after) the peak candidate position of a r.m.s. signal-related small quantity.
- ◆ Require that the amplitude at the peak candidate position is larger than a r.m.s. signal-related small quantity and the amplitude difference among the peak candidate and the previous (next) signal amplitude is larger (smaller) than a r.m.s. signal-related small quantity.

NOTE:

- ◆ R.m.s. is a measurements of the noise level in the analog signal

0°, nominal HV+20, 90%He-10%iC₄H₁₀
Tube with 1-cm cell size and 20 μ m diameter

2021/2022 testbeam: find electron peaks algorithms

Find good electron peak candidates at **position bin n** and amplitude A_n :

RUNNING TEMPLATE ALGORITHM (RTA)

- Define an electron pulse template based on experimental law with a raising and falling exponential over a fixed number of bins (K_{tot}) and digitized ($A(k)$) according to the data sampling rate.
- Run over K_{tot} bins by comparing it to the subtracted and normalized data (build a sort of χ^2 and define a cut on it).
- Subtract the found peak to the signal spectrum and iterate the search and stop when no new peak is found.

30°, nominal HV+20, 90%He-10%iC₄H₁₀
Tube with 1 cm cell size and 20 μm diameter

2 cm drift tube Track angle 45°

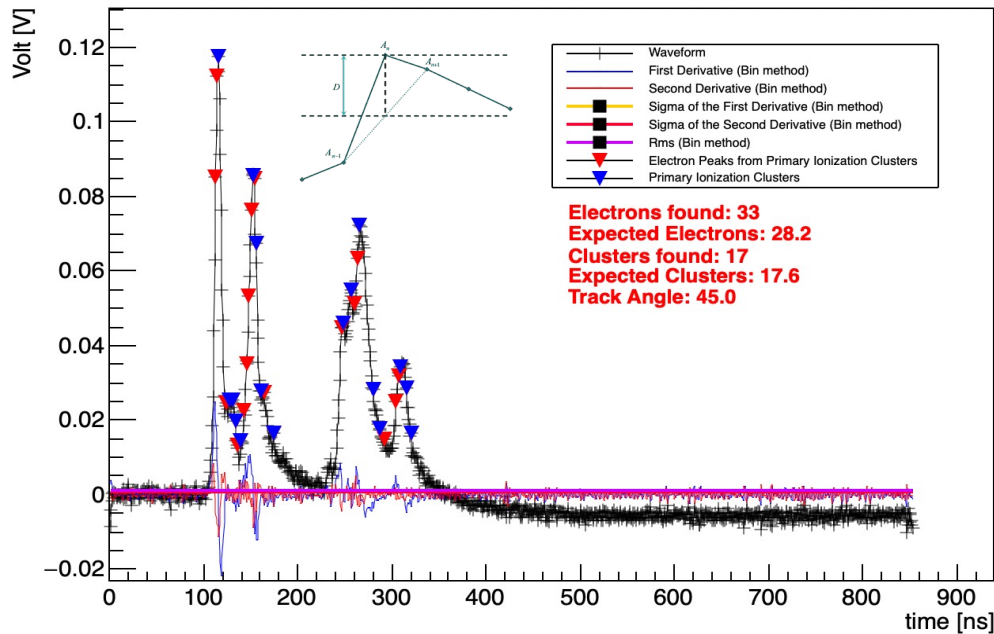

1 cm drift tube Track angle 45°

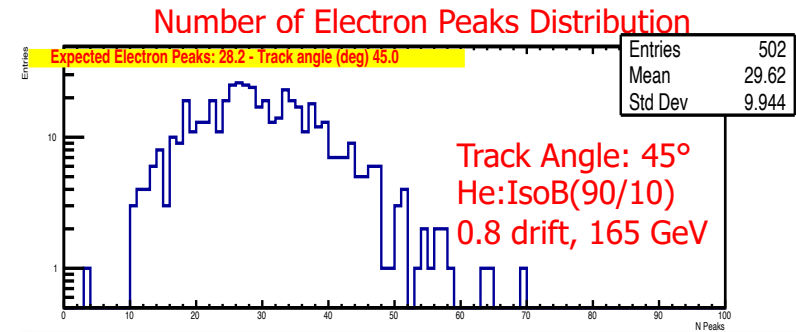

2021/2022 testbeam: number of electron peaks

Reconstruction of Electron Peaks (DERIV Algorithm)

Sense Wire Diameter 10 μm – Cell Size 1.0 cm – Track Angle 45° –
 1.2 GSa/s – Gas Mixture He: IsoB 90/10 – 165 GeV

Expected number of electrons = δ cluster/cm (M.I.P.) \times
 drift tube size [cm] \times 1.6 (cluster size) \times 1.3 (relativistic
 rise) \times $1/\cos(\alpha)$

- α is the angle of the muon track w.r.t. normal direction to the sense wires
- δ cluster/cm (mip) changes from 12, 15, 18 respectively for He: IsoB 90/10, 85/15 and 80/20 gas mixtures
- Actual drift tube size are 0.8, 1.2, and 1.8 respectively for 1 cm, 1.5 cm, and 2 cm cell size tubes

2021/2022 testbeam: clusterization

CLUSTERIZATION algorithm: Reconstruction of Primary Ionization Clusters

- Merging of electron peaks in consecutive bins in a single electron to reduce fake electrons counting
- Contiguous electrons peaks which are compatible with the electrons' diffusion time (it has a $\sim\sqrt{t_{ElectronPeak}}$ dependence, different for each gas mixture) must be considered belonging to the same ionization cluster. For them, a counter for electrons per each cluster is incremented.
- Position and amplitude of the clusters corresponds to the position and height of the electron having the maximum amplitude in the cluster. \rightarrow Poissonian distribution for the number of clusters!

Electron per Clusters Distribution

Sense Wire Diameter 20 μm – Cell Size 1.0 cm – Track Angle 60° – 1.2 GSa/s – Gas Mixture He:IsoB 90/10 – 165 GeV

2021/2022 testbeam: number of clusters

Sense Wire Diameter 10 μm – Cell Size 1.0 cm
 – Track Angle 45° – 1.2 GSa/s – Gas Mixture
 He: IsoB 90/10 – 165 GeV

- Poissonian behaviour
- Measurements and predictions about the number of clusters are in very good agreement, with 1cm cell size

Number of Cluster Distribution

Expected number of cluster = δ cluster/cm (MIP) \times drift tube size [cm] \times 1.3 (relativistic rise) \times $1/\cos(\alpha)$

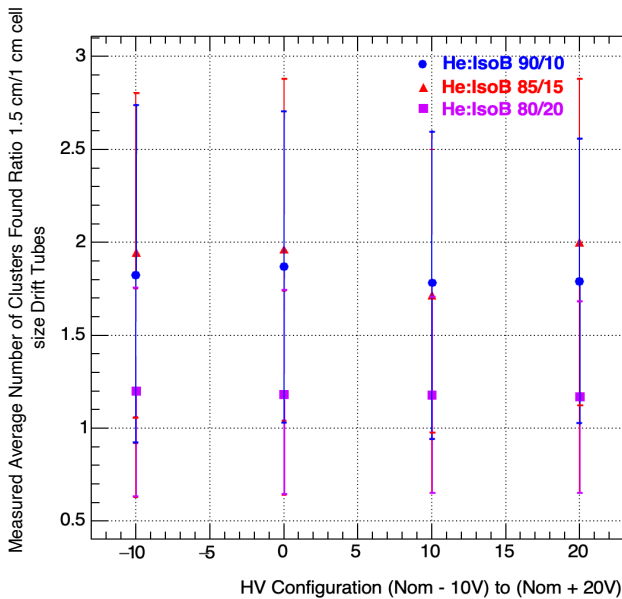

- α is the angle of the muon track w.r.t. normal direction to the sense wires
- δ cluster/cm (mip) changes from 12, 15, 18 respectively for He: IsoB 90/10, 85/15 and 80/20 gas mixtures
- Actual drift tube size are 0.8, 1.2, and 1.8 respectively for 1 cm, 1.5 cm, and 2 cm cell size tubes

Beam test results: recombination and attachment

Efficiency w.r.t. Expected Number of Electrons (Clusters) above ~85%. What about being independent from theoretical assumptions?

in Ratios

Expected number of cluster = δ cluster/cm (MIP) \times drift tube size [cm] \times 1.3 (relativistic rise) \times $1/\cos(\alpha)$

Space charge + attachment + recombination effects affect the experimental CC efficiency!

- The **loss of efficiency at small angles** is due to the partial shielding of the electric field due to the space charge.
- The **loss of efficiency at large angles** is partially due to the fact that increasing the number of clusters in the same drift time, increases the probability of pileup, then decreasing the counting efficiency.
- The **lower counting efficiency in 2cm** tubes compared to 1cm ones is only partially explained by the effects of recombination and attachment; other possible effects under investigation

Beam test results: recombination and attachment

Number of Clusters found by DERIV+CLUSTER algorithms

Average Number of Clusters found(@drift time) vs drift time

Combined action of recombination, electron attachment and E-field suppression due to space charge

Beam test results: applying corrections

Cuts on the derivative algorithm, which were optimized without including the recombination and attachment effects, need to be reformulated.

Also, these corrections, strongly depend on the drift length and, therefore, on the drift tube size and must be calculated for each different drift tube configuration.

First attempt of re-tuning cuts on the DERIV algorithm for a 1 cm cell size drift tube

Cluster counting simulated in Geant4

Goal: to implement the cluster counting algorithm for the simulation of the drift chamber in the Geant4 IDEA Full SIM framework. The basic idea is to develop an algorithm which can use the energy deposit information provided by Geant4 to reproduce, in a fast and convenient way, the cluster number distribution and the cluster size distribution. Muons at 300 MeV traversing 200 cells, are used for the validation. The results obtained from Geant4 are in a good agreement with the ones from Garfield and with the expectation.

https://agenda.infn.it/event/35315/contributions/194914/attachments/103560/144927/IDEA_DC_Mar23.pdf

N:B. The absolute value of the expected energy deposit to be crosschecked

Geant4 vs DD4HEP: comparison

- **Goal:** to validate the implementation of the IDEA drift chamber (DC) geometry and its reconstruction in the DD4hep by doing a comparison with the Geant4 framework. Muons at 10 GeV are used for the validation. Good agreement is observed between the results from the two frameworks.

Hybrid RNN/CNN for robust PID based on dN/dx cluster counting in drift chambers

A two-step Deep-Learning Reconstruction Algorithm for Cluster Counting

RNN (Recurrent Neural Network)

RNN for peak finding

- The peak finding algorithm shows better signal purity and efficiency than derivative algorithm

- The clusterization algorithm gives Gaussian distributed number of clusters

- By applying the algorithms, single cell resolution is close to the MC truth level

CNN for peak clustering

determine the number of clusters per particle trajectory.

- Preliminary result with beam test data seems good

https://indico.jlab.org/event/459/contributions/11749/attachments/9370/14005/slides_CHEP2023.pdf

Next plans

Hardware:

- setup of drift tubes for **testbeam 2024 at CERN and Fermilab**
- **construction of a full scale DCH prototype**

Simulation and design:

- full simulation (**geometry, hits, digi**) of the DCH and cluster counting
- **finalization** of the mechanical design of the DCH

Testbeam data analysis:

- finalization of testbeam analysis with 2021, 2022 and 2023 data

Summary and conclusions

- PID with a cluster counting technique is under study by using simulations and beam-test data
- Several algorithms for peak finding under development show agreement in data
- Results demonstrate the capability to count cluster with high efficiency at a fixed $\beta\gamma$
- Limiting conditions for an efficient cluster counting established:
 - gas gain saturation
 - cluster density (by changing the gas mixture)
 - space charge (gas gain, sense wire diameter, track angle)
 - recombination effects and electron attachment
- PID with a cluster counting technique simulated in Geant4/DD4HEP and Delphes

Short term prospects:

- Continuation of Beam Tests
- Construction of a prototype of a full scale wedge of the drift chamber:

Notes in preparation:

- IDEA drift chamber proposal
- Results from cluster counting beam test
- Data acquisition system for cluster counting
- Preliminary studies on the IDEA drift chamber mechanical structure
- Preliminary estimate of the IDEA drift chamber costing
