

# SPLENDOR: Narrow-gap semiconductors for light DM

Yoni Kahn (UIUC)

ALPS2024, 4/4/24

# Sub-GeV DM: we are approaching our targets!

but so far  $< 1$  MeV  
is wide open

# Sub-GeV DM: a universe of constraints

One in a billion late-time DM annihilations would ionize half the universe!

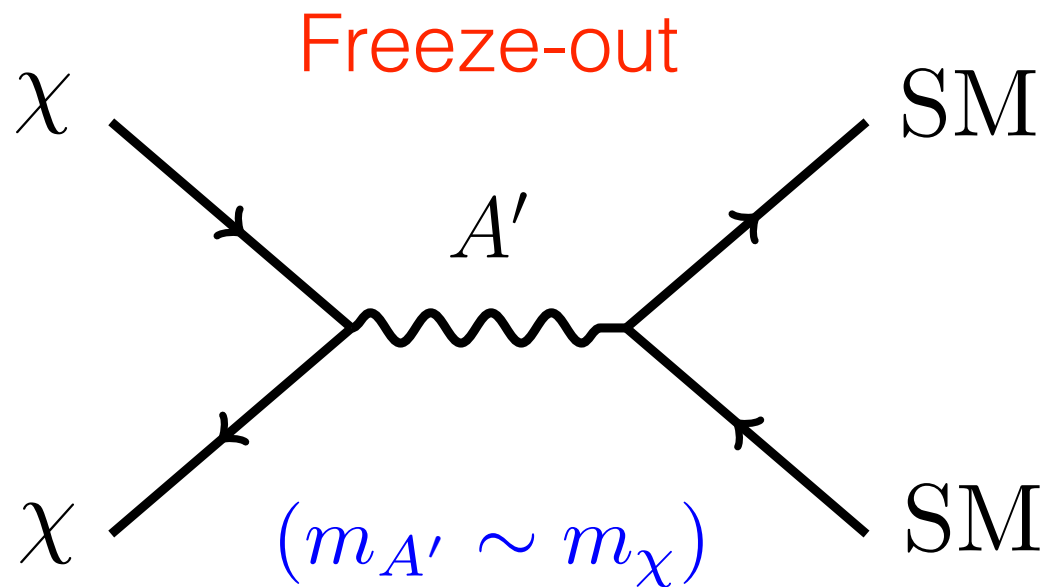

Extra stuff at  $T \sim \text{MeV}$  changes expansion rate of universe during BBN

Need a particle physics model with a consistent thermal history to make sense of experiments

# Dark photon benchmark

$$\mathcal{L} \supset -\frac{m_{A'}^2}{2} A'_\mu A'^\mu + A'_\mu (\kappa e J_{\text{EM}}^\mu + g_D J_D^\mu)$$

DM is a scalar or Majorana fermion,  $m_\chi \gtrsim 5 \text{ MeV}$

DM never in chemical equilibrium:  
no constraints on mass or spin

In both cases, non-relativistic limit is a coupling to charge density:

$$\hat{H}_{\text{int}} = \int \frac{d^3 \mathbf{q}}{(2\pi)^3} e^{i\mathbf{q} \cdot \hat{\mathbf{r}}_x} V(\mathbf{q}) \hat{\rho}(\mathbf{q})$$

← Yukawa potential  
← SM charge density

# Is your detector a bag of free particles?

$$v_{\text{DM}} \sim 10^{-3} \implies p_{\text{DM}} \simeq 10^{-3} m_{\text{DM}}, \quad E_{\text{DM}} \simeq 10^{-6} m_{\text{DM}}$$

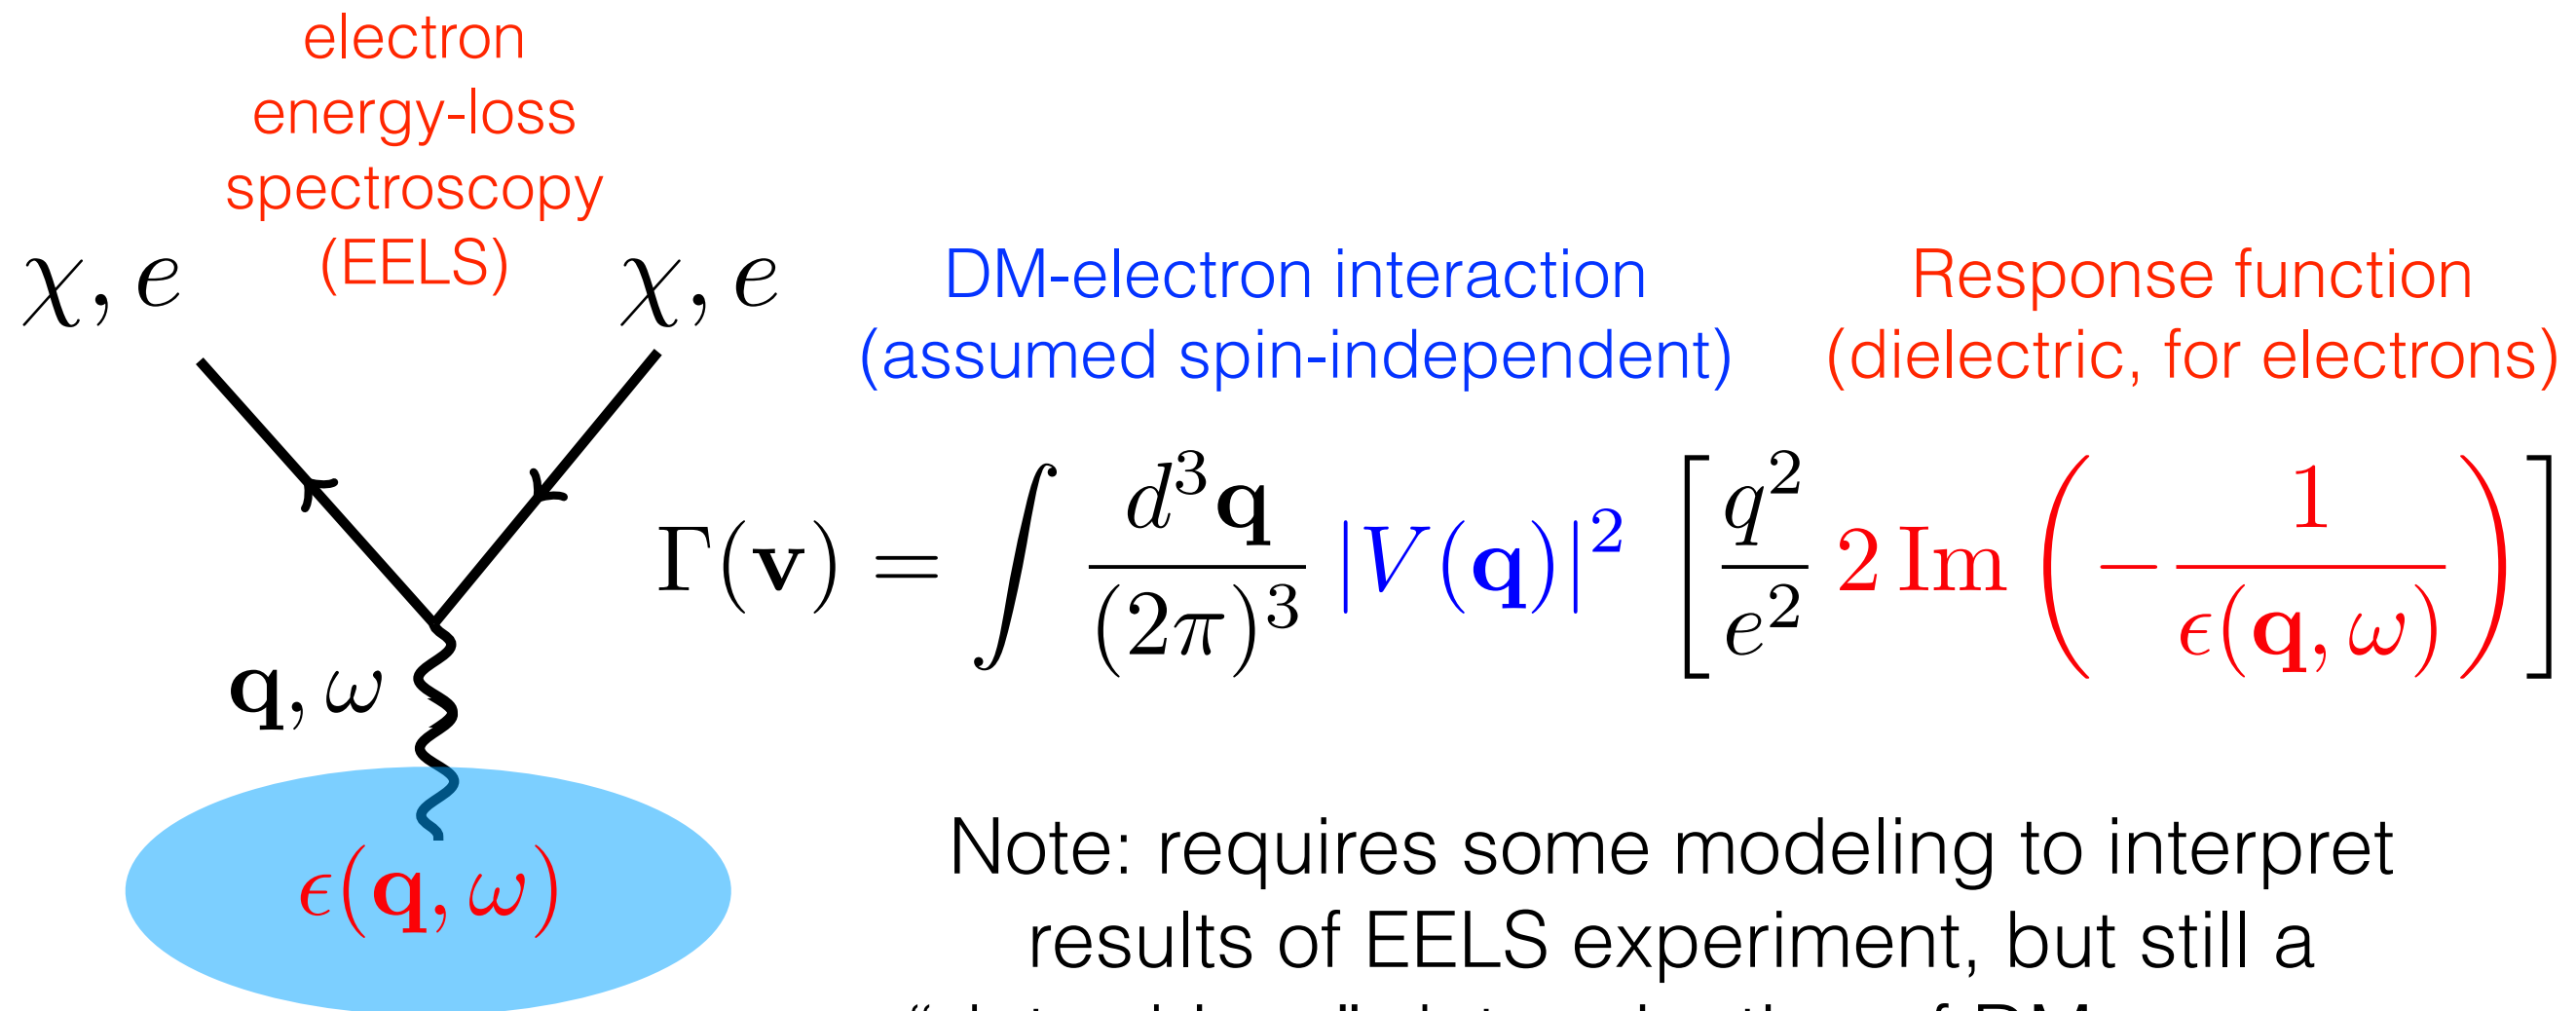

“Free” =  $E_{\text{DM}}, p_{\text{DM}}$  are the largest scales in the system.

Sub-MeV detection via electron scattering: novel materials!

# Measuring electron response

Just like deep inelastic scattering lets us measure strong QCD effects with QED probes, electrons can act as “proxy” for DM

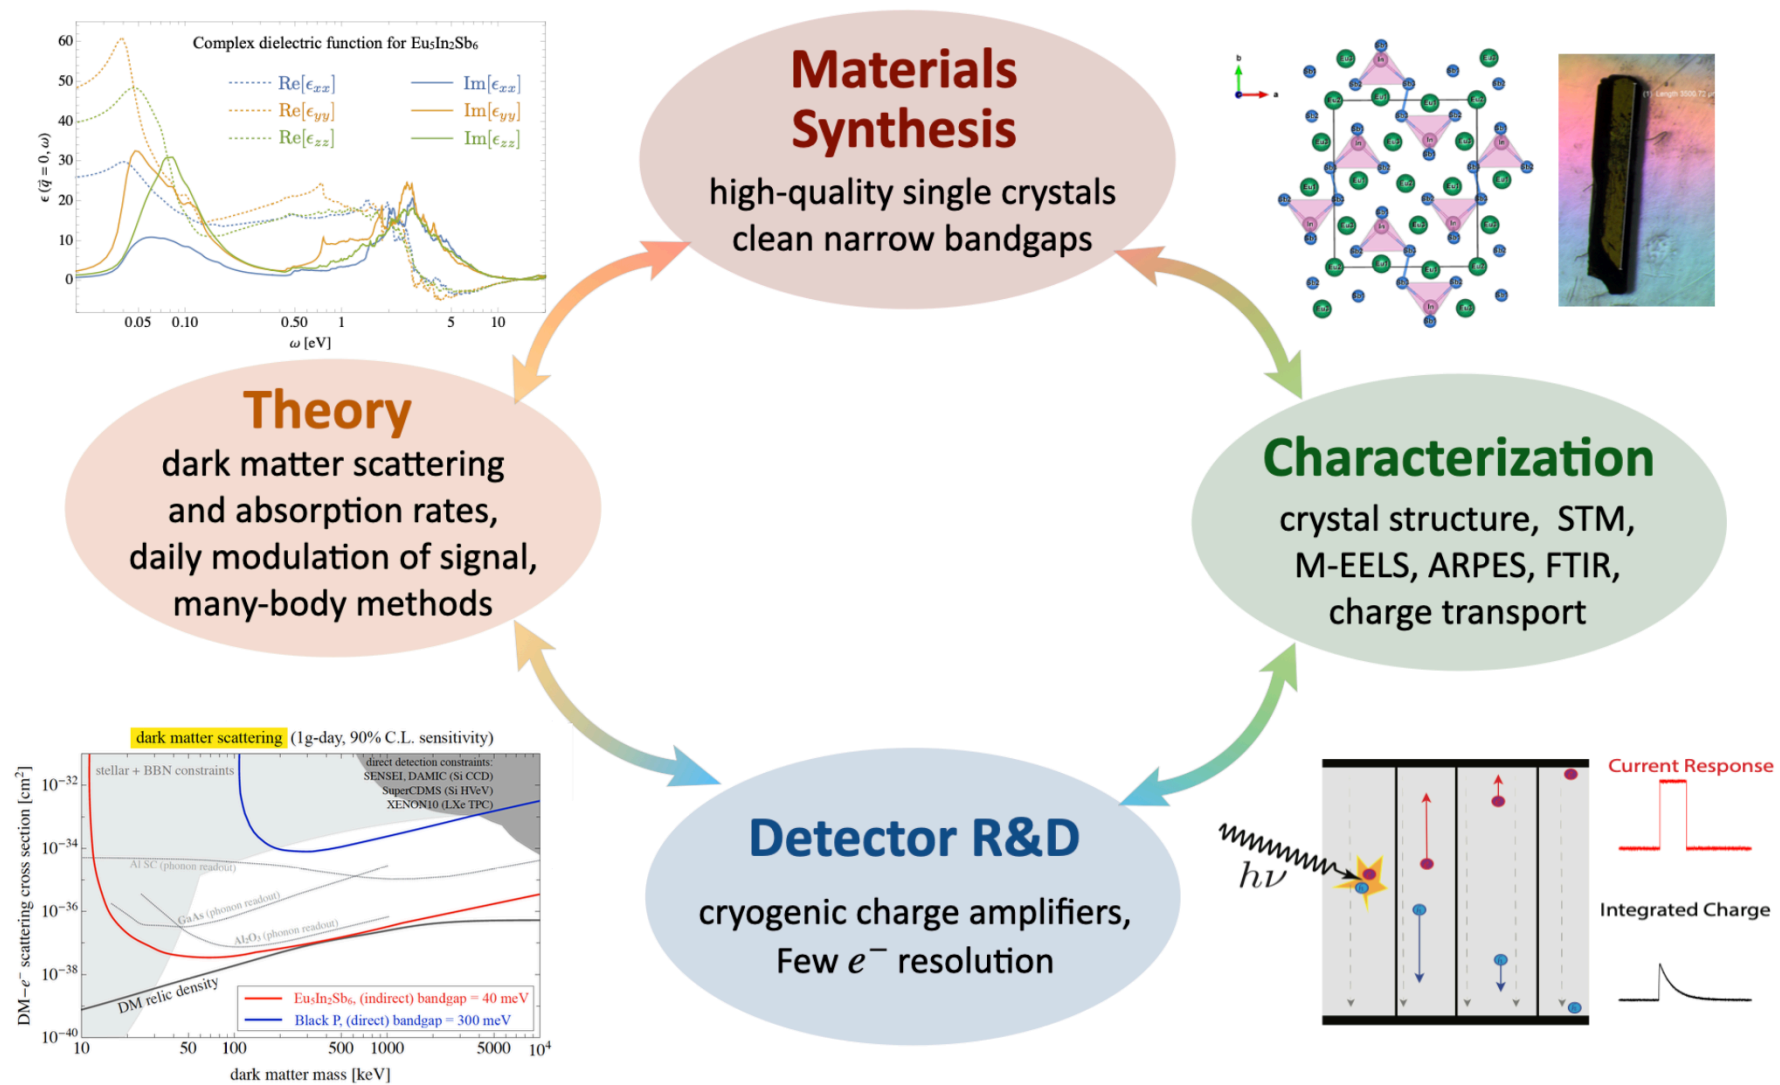

$$\Gamma(\mathbf{v}) = \int \frac{d^3 \mathbf{q}}{(2\pi)^3} |V(\mathbf{q})|^2 \left[ \frac{q^2}{e^2} 2 \operatorname{Im} \left( -\frac{1}{\epsilon(\mathbf{q}, \omega)} \right) \right]$$

Note: requires some modeling to interpret results of EELS experiment, but still a “data-driven” determination of DM response

# The SPLENDOR program

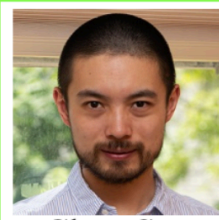

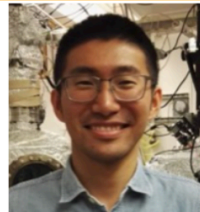

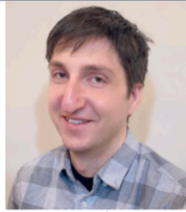

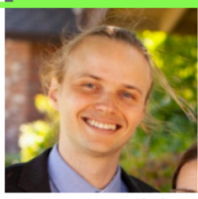

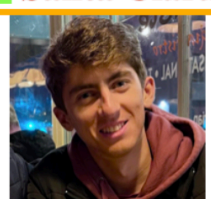

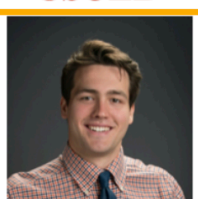

Search for **P**articles of **L**ight dark matt**E**r with **N**arrow-gap semicon**D**uct**O**rs

Goal: sub-MeV DM-electron scattering at the freeze-in target via charge detection in sub-eV-gap materials

# The SPLENDOR team

Amazing work by all of these people, won't cite everyone by name in this talk: **this is a true team effort!**

# Materials synthesis: candidates

linear scale

**ZrTe<sub>5</sub>**

factor of **10** increase in resistivity from 300 K → 10 K, indicating in-gap impurities and high dark currents

B. Xu *et al.*, *Phys. Rev. Lett.* **121**, 2018

log scale!!

**Eu<sub>5</sub>In<sub>2</sub>Sb<sub>6</sub>**

factor of **10<sup>7</sup>** increase in resistivity from 300 K → 10 K, indicating clean gap and strongly suppressed dark currents

PFS Rosa, SM Thomas, ..., F Ronning, *npj Quantum Materials* **5**, 52 (2020).

**La<sub>3</sub>Cd<sub>2</sub>As<sub>6</sub>**

factor of **10<sup>14</sup>** increase in resistivity from 300 K → 10 K, indicating clean gap and strongly suppressed dark currents

MM Piva, SM Thomas, ..., F Ronning, PFS Rosa, *Chemistry of Materials* **33**, 4122 (2021).

When we first went looking for a narrow-gap material, ZrTe<sub>5</sub> seemed promising, but these lanthanides are **exponentially** better!

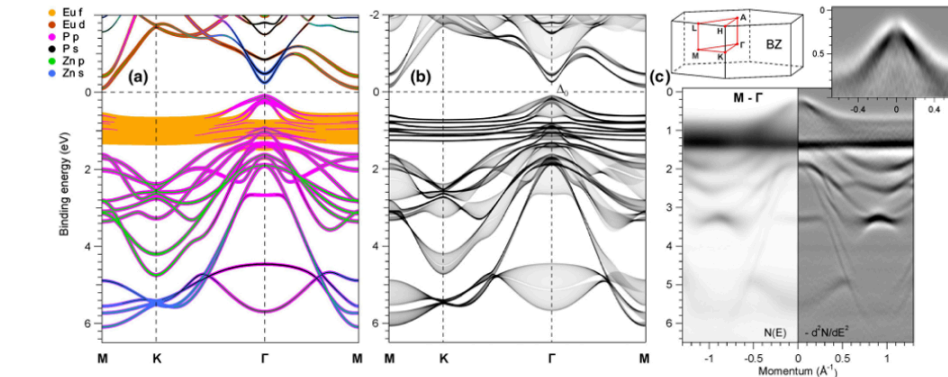

# Materials synthesis: in practice

## Zintl phase (Proposed)

PFS Rosa *et al.*, *npj Quantum Materials* **5**, 52 (2020).

## Zintl phase (Cleavable)

Kreber *et al.* *Phys. Rev. B* **108**, 045116 (2023).

## Black Phosphorus (benchmark)

Guan *et al.* *Phys. Rev. B* **94**, 045414 (2016).

All viable for ~gram-scale crystals!

# Characterization: benchmarking

Validate pipeline on black phosphorus (0.3 eV gap):

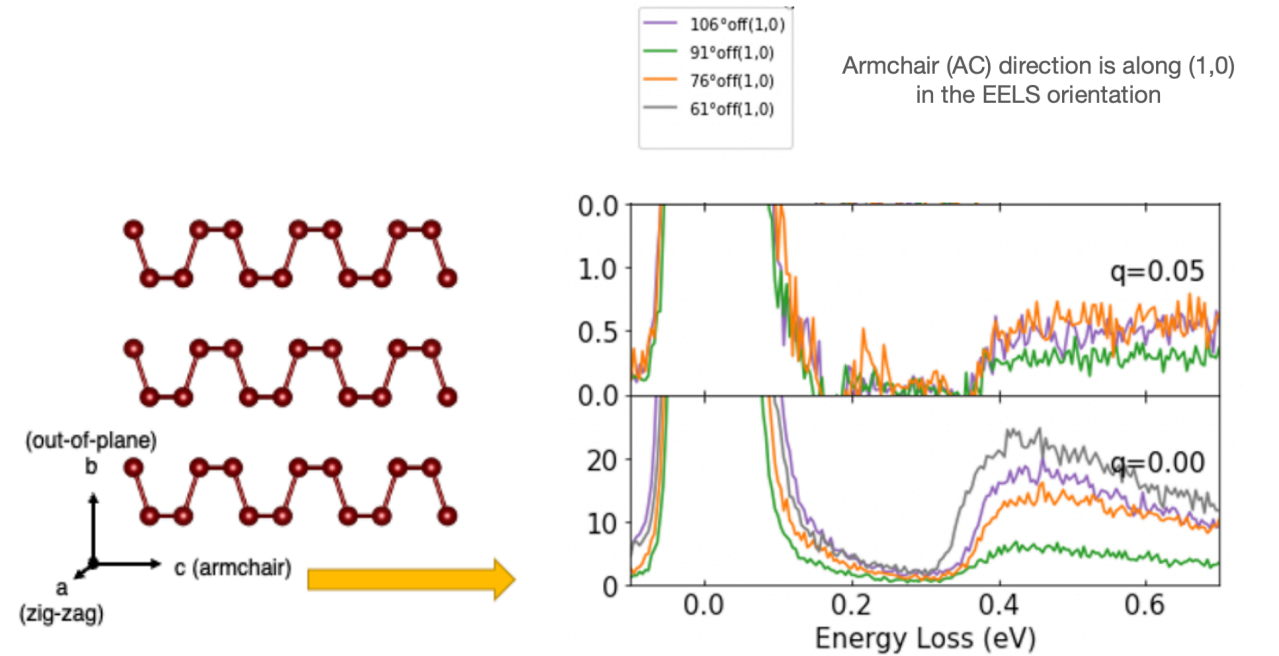

EELS  
( $q = 0$ )

two-band  
model

EELS (finite  $q$ )

DFT

Excellent agreement for both direct gap and anisotropy

# Characterization of $\text{EuZn}_2\text{P}_2$

Pristine  $\text{EuZn}_2\text{P}_2$

$$E_g^{\text{direct}} = 610 \text{ meV}$$

$$E_g^{\text{indirect}} = 244 \text{ meV}$$

EELS nails the direct gap,  
but **indirect gap is tricky**:  
finite momentum probes surface  
rather than bulk

Activated behavior

$$\rho(T) = Ae^{\Delta/k_B T}$$

Lightly doped  
Semiconductors

$$\rho(T) = A \exp[(T_0/T)^\beta]$$

# Characterization: band gap

M-EELS q range

DFT predicted indirect gap location

$$q_{\min} = \frac{\omega_{\min}}{v_{\max}} \simeq 36 \text{ eV} \left( \frac{\omega_{\text{gap}}}{100 \text{ meV}} \right)$$

Strategy: validate DFT by measuring direct gap and anisotropy, then use DFT to extract finite-q response relevant for DM scattering

# Characterization of $\text{Eu}_5\text{In}_2\text{Sb}_6$

Hall effect: fit with 30 meV gap

Resistivity is exponential

Mobility at 2 K  $\mu_h = \mathcal{O}(10) \text{ V}\cdot\text{cm}^2/\text{s}$

Material doesn't cleave well, so EELS only measures a gap averaged over entire BZ

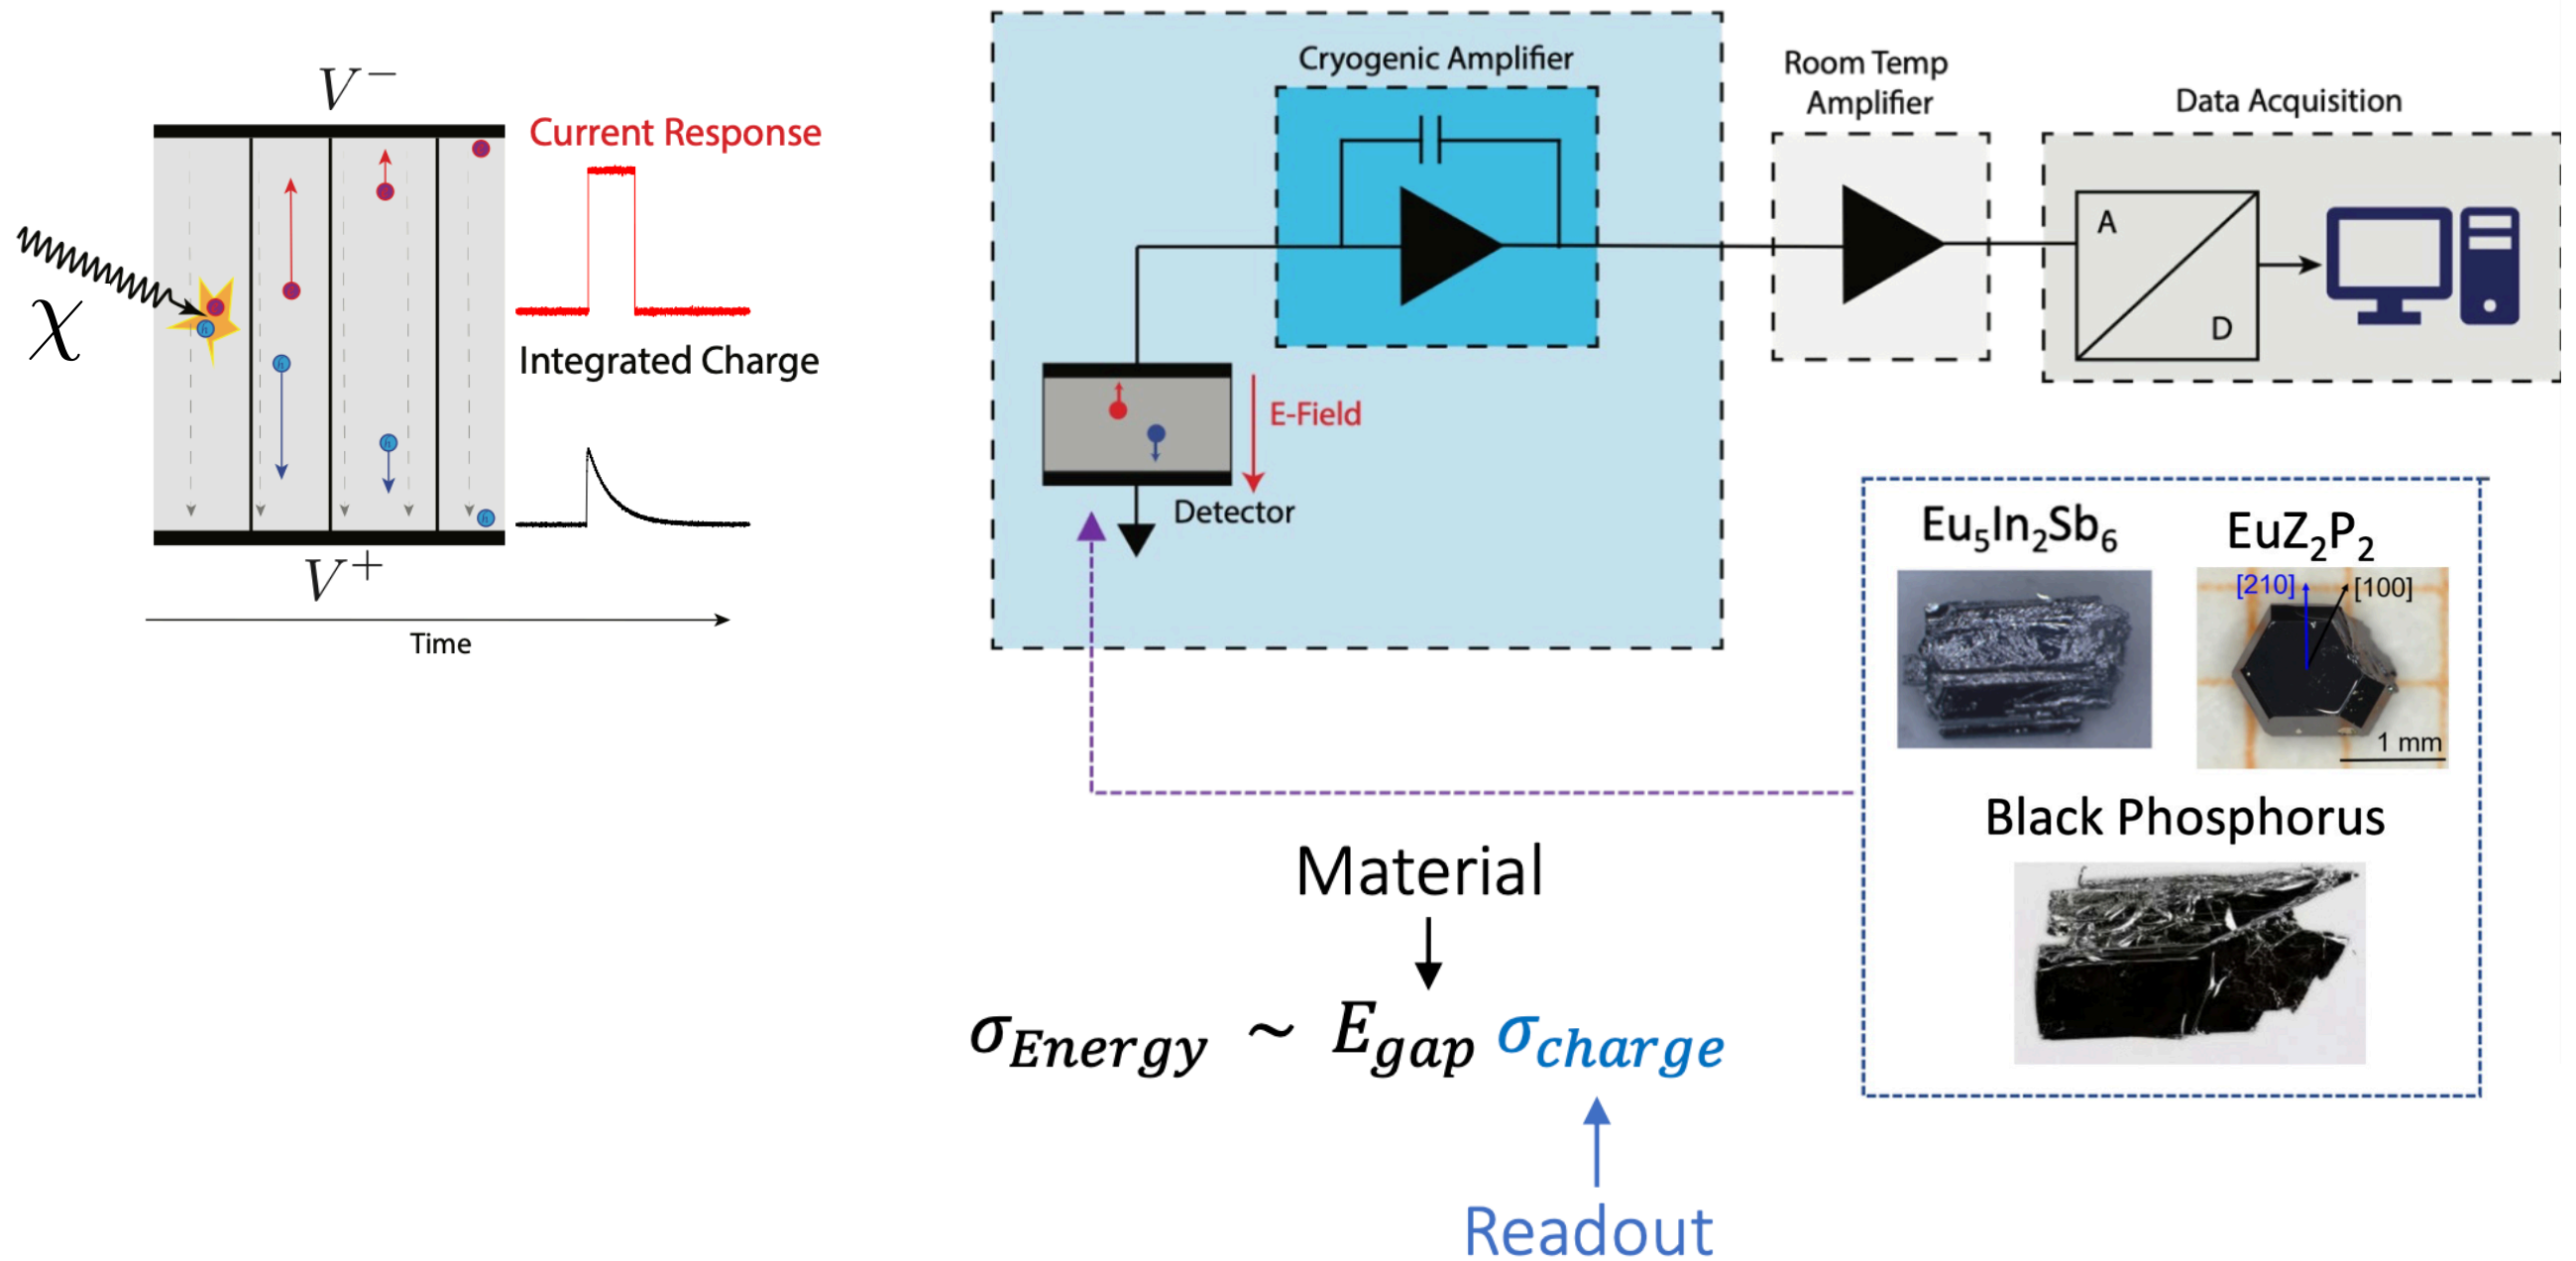

# Characterization: summary

	<b>Eu<sub>5</sub>In<sub>2</sub>Sb<sub>6</sub></b>	<b>EuZn<sub>2</sub>P<sub>2</sub></b>	<b>Black Phosphorus</b>
<b>Mobility</b>	$\mu_h = \mathcal{O}(10) \text{ V.cm}^2/\text{s}$	$\mu_h = \mathcal{O}(1) \text{ V.cm}^2/\text{s}$	$\mu_h = \mathcal{O}(0.1) \text{ V.cm}^2/\text{s}$
<b>Direct Gap (EELS)</b>	600-800meV	620 meV	<b>300 meV</b>
<b>Direct Gap (FTIR)</b>	500 meV	330 meV	<b>340 meV</b>
<b>Direct Gap (Theory)</b>	<b>40 meV</b>	610 meV	<b>300 meV</b>
<b>Indirect Gap (EELS)</b>	Upcoming sputtering/ annealing system for finite-q experiments	Upcoming higher-resolution higher-q experiments	N/A
<b>Indirect Gap (FTIR)</b>	<b>60 meV</b>	<b>90 meV</b>	N/A
<b>Indirect gap (Theory)</b>	<b>20 meV</b>	240 meV (smaller with strain)	N/A
<b>Charge gap (Transport)</b>	<b>42 meV</b>	<b>18 - 100 meV</b>	-

our desired detector material: indirect gap likely 20-60 meV

# Detector concept

Goal: “universal” capacitive charge amplifier with few e- resolution

# Detector: current status

## Amplifier Prototype Testing

Testing of complete amplifier in dilution refrigerator – **DONE!**

Integrated measured voltage noise across expected capacitance results in charge resolution of 7 electrons

Reduction of EMI should give 2-3 electron resolution!

$$\sigma_{charge} \sim N_V \left( C_{parasitic} + C_{input} + C_{detector} \right) \sim 5-10 \text{ pF}$$

Just put out paper on progress of charge amp!

# Theory: reach projections

Assuming 20 meV gap:

# Theory: daily modulation

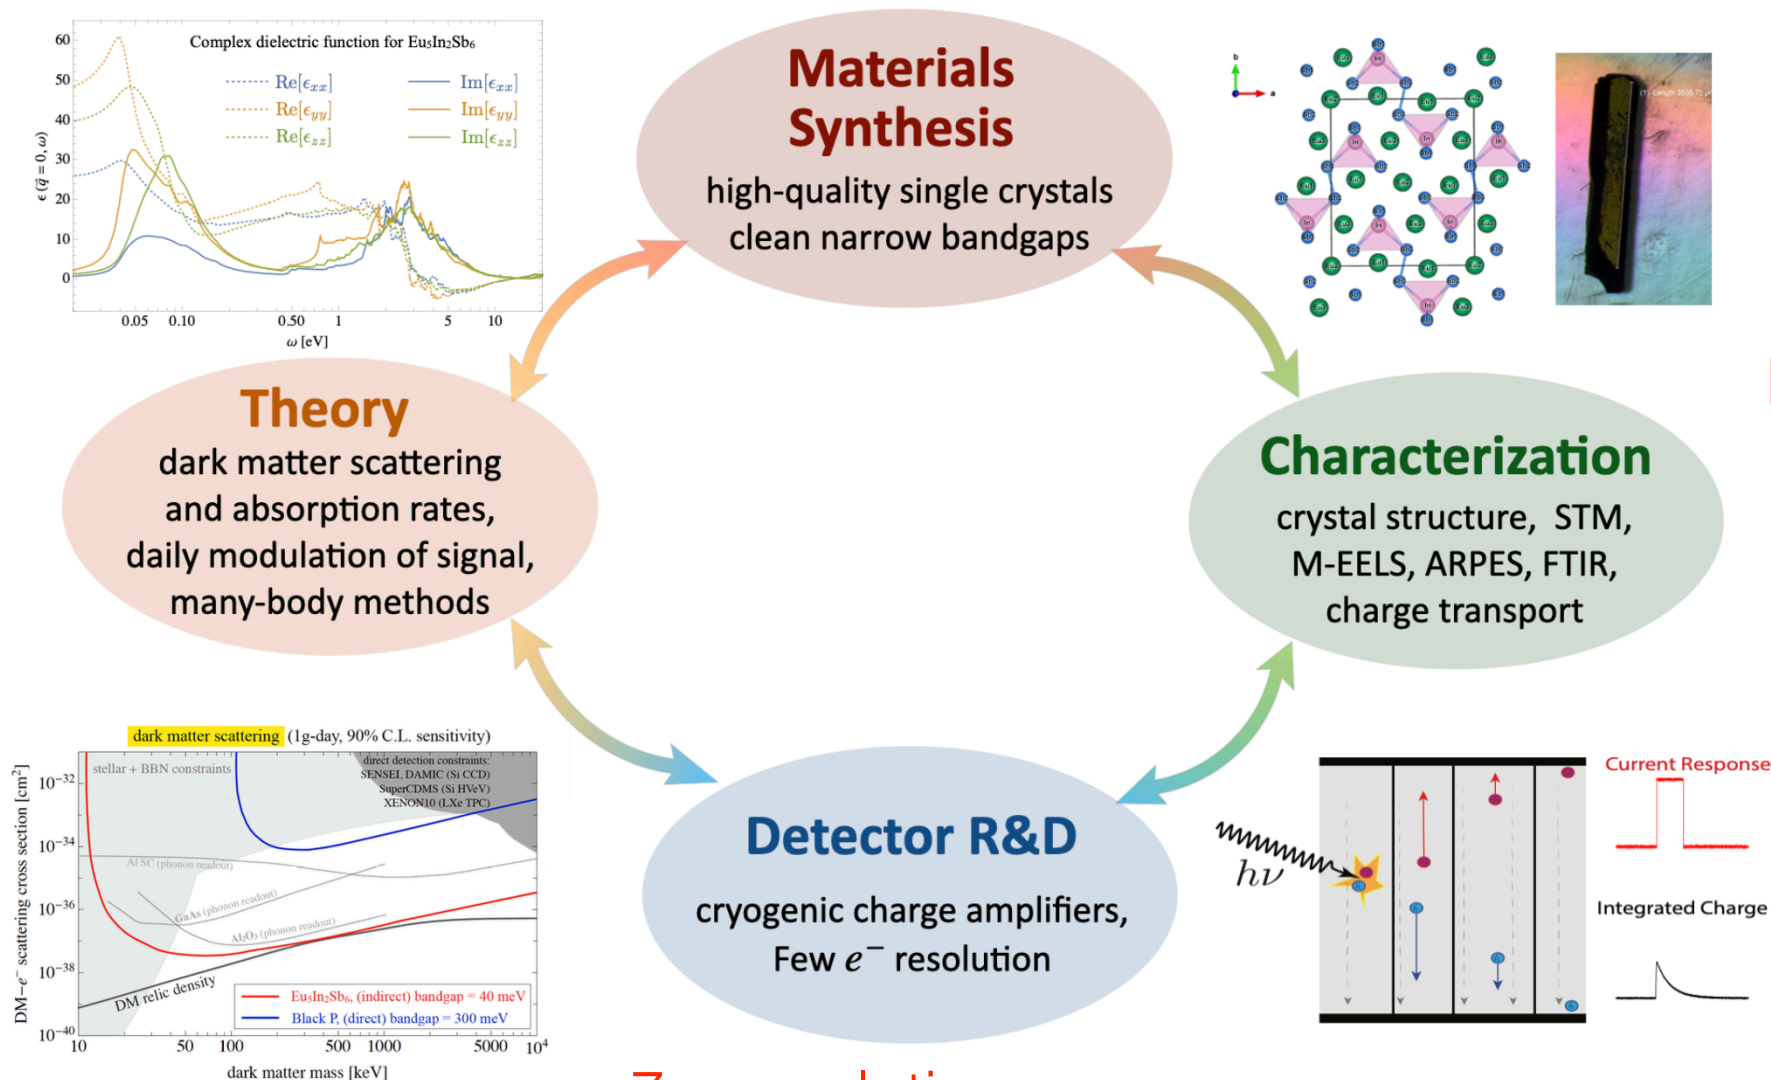

Expect ~20% daily modulation (full calculation forthcoming)

# Conclusion

two candidate materials  
plus commercially-purchased  
benchmark

Potential for  
first DM search  
below 500 keV

EELS works!  
But must be  
combined  
with theory  
modeling

7 $e^-$  resolution now,  
expect 2 or 3  $e^-$

Paper coming this summer, stay tuned!

Backup

# Response functions

(insert your favorite detector here)

Energy deposited by DM:

$$\omega_{\mathbf{q}} = \frac{\mathbf{p}^2}{2m_\chi} - \frac{(\mathbf{p} - \mathbf{q})^2}{2m_\chi} = \mathbf{q} \cdot \mathbf{v} - \frac{q^2}{2m_\chi}$$

if your target is not a free particle, it is not a momentum eigenstate!

# Response functions

Energy deposited by DM:

$$\omega_{\mathbf{q}} = \frac{\mathbf{p}^2}{2m_\chi} - \frac{(\mathbf{p} - \mathbf{q})^2}{2m_\chi} = \mathbf{q} \cdot \mathbf{v} - \frac{q^2}{2m_\chi}$$

does the target have an energy eigenstate at  $\omega_{\mathbf{q}}$ ?

$$S(\mathbf{q}, \omega_{\mathbf{q}}) \propto \sum_f |\langle f | \sum_j e^{i\mathbf{q} \cdot \mathbf{r}_j} | i \rangle|^2 \delta(\omega_f - \omega_{\mathbf{q}})$$

$$R \sim \int d^3 \mathbf{v} f(\mathbf{v}) \int d^3 \mathbf{q} F^2(\mathbf{q}) S(\mathbf{q}, \omega_{\mathbf{q}})$$

DM properties

Material properties

General framework that works for **any** many-body system

# Sub-GeV DM kinematics

Under-explored energy/momentum regime: too high for CM, too low for materials science
