Thank Profs. H.-n. Li and Z.J. Xiao for collaborations

June
2023

OUTLINE

1. Introduction and Motivation
2. Perturbative Calculations
3. Results and Discussions
4. Summary and Outlook

INTRODUCTION and MOTIVATION

- ◆ A B_c meson is different from the typical heavy-light B meson and heavy-heavy quarkonia. The B_c -meson decays contain rich heavy quark dynamics in perturbative and non-perturbative regimes.

◆ From the experimental side,

- ‡ The first discovery of Bc meson at Tevatron in 1998 proclaimed the beginning of its experimental studies.
- ‡ And, the running of LHC since 2009 promoted the measurements on Bc-meson decays to further understand the heavy flavor physics.
- ‡ The LHC experiments have measured many multi-body nonleptonic Bc-meson decays through relative ratios of the branching fractions between the related Bc decays.
- ‡ Some interesting results have been reported. Typically,

See Pereima's talk

☑ Bc- \rightarrow J/ ψ K

$$R_{K/\pi}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.069 \pm 0.020 ,$$

LHCb arXiv:1306.6723

$$R'_{K/\pi}{}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.079 \pm 0.008 .$$

LHCb arXiv:1607.06823

☑ Bc-→J∧psi π+π-π+

Exhibits an *a1* peak

$$R_{3\pi/\pi}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 2.41 \pm 0.45 ,$$

LHCb

arXiv:1204.0079

$$R'_{3\pi/\pi}{}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 2.55 \pm 0.87 ,$$

CMS

arXiv:1410.5729

$$R_{3\pi/\pi}^{\text{Avg}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 2.45 \pm 0.40 ,$$

HFLAV

arXiv:2206.07501

☑ Bc-→J∧psi K+K-π+

$$R_{2K\pi/\pi}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+ K^- \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.53 \pm 0.11 ,$$

LHCb

arXiv:1309.0587

☑ Bc-→J∧psi K+K-π+ and Bc-→J∧psi π+π-π+

$$R_{2K\pi/3\pi}^{\text{Exp}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+ K^- \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)} = 0.185 \pm 0.014 .$$

◆ From the theoretical side,

‡ Partial decay modes such as $B_c \rightarrow J/\psi P$, $J/\psi V$ and $J/\psi a_1$ have been investigated mainly based on naïve factorization in many different models, but the predictions of the individual branching fractions vary in a wide range.

‡ Most of the relative ratios between the branching fractions of these mentioned B_c -meson decays and $B_c \rightarrow J/\psi \pi$ are basically consistent with each other within errors, despite their individual decay rates with large discrepancies.

‡ For the $B_c \rightarrow J/\psi P$ decays for example,

$$R_{K/\pi} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} \simeq \frac{|V_{us}|^2}{|V_{ud}|^2} \cdot \frac{f_K^2}{f_\pi^2} \sim 0.081 ,$$

‡ However, for the decays with suppressed or vanished factorizable emission amplitudes while with enhanced nonfactorizable ones such as $B_c \rightarrow J/\psi S$, $B_c \rightarrow J/\psi T$, and so on, we should go beyond naïve factorization to explore the rich but complicated dynamics within the factorization framework based on QCD.

‡ The applications of conventional PQCD approach to the B_c -meson decays have been reviewed shortly in 2014.

Xiao and Liu, arXiv:1401.0151

‡ But, the finite charm quark mass makes the B_c meson more complicated than the typical B mesons. Two important ingredients are demanded to further improve the PQCD formalism:

✓ appropriate Bc-meson distribution amplitude to highly suppress the strong phase in the Bc to J/psi transition form factor;

Liu, Li, and Xiao, arXiv:1801.06145

$$\phi_{B_c}(x, b) = \frac{f_{B_c}}{2\sqrt{2}N_c} N_{B_c} x(1-x) \exp \left[-\frac{(1-x)m_c^2 + xm_b^2}{8\beta_{B_c}^2 x(1-x)} \right] \exp \left[-2\beta_{B_c}^2 x(1-x)b^2 \right],$$

Figure 2 Behavior of Bc-meson distribution amplitude on the shape parameter: black-solid, red-dashed and blue-dotted lines correspond to $\beta_{B_c} = 0.9, 1.0, 1.1$, respectively.

✓ new Sudakov factor for Bc-meson decays derived by resumming the term $\ln(mb/mc)$, in addition to the ordinary one $\ln(mb/\Lambda_{\text{QCD}})$.

Liu, Li, and Xiao, arXiv:2006.12786

$$S_c(Q, b) = \frac{a_1}{2\beta_1} \left\{ \hat{Q} \ln \hat{Q} - \hat{c} \ln \hat{c} - (\hat{Q} - \hat{c})(1 + \ln \hat{b}) \right\} \\ + \frac{a_2}{4\beta_1^2} \left\{ -\ln \frac{\hat{Q}}{\hat{c}} + \frac{\hat{Q} - \hat{c}}{\hat{b}} \right\} + \frac{a_1}{4\beta_1} \ln \frac{\hat{Q}}{\hat{c}} \ln \frac{e^{2\gamma_E - 1}}{2}$$

Liu, arXiv:2305.00713

$$\hat{Q} \equiv \ln [xP^+/\Lambda], \quad \hat{c} \equiv \ln [m_c/(\sqrt{2}\Lambda)], \quad \text{and} \quad \hat{b} \equiv \ln [1/(b\Lambda)],$$

Notice that, when the replacement $\hat{c} \rightarrow \hat{b}$ is adopted, then the formula will recover the Sudakov factor for B-meson decays with one-loop running coupling at next-to-leading-logarithm accuracy.

✦ Hence, the improved PQCD (iPQCD) formalism is more self-consistent at leading order and is also ready for the decays B and Bc to charmonia plus light mesons.

PERTURBATIVE CALCULATIONS

- ◆ The weak effective Hamiltonian could be written as,

$$H_{\text{eff}} = \frac{G_F}{\sqrt{2}} \left\{ V_{cb}^* V_{uq} [C_1(\mu) O_1(\mu) + C_2(\mu) O_2(\mu)] \right\} + \text{h.c.} ,$$

with local four-quark operators

$$O_1 = \bar{q}_\alpha \gamma_\mu (1 - \gamma_5) u_\beta \bar{c}_\beta \gamma_\mu (1 - \gamma_5) b_\alpha , \quad O_2 = \bar{q}_\alpha \gamma_\mu (1 - \gamma_5) u_\alpha \bar{c}_\beta \gamma_\mu (1 - \gamma_5) b_\beta ;$$

- ◆ The standard procedures in the PQCD approach are utilized in the $B_c \rightarrow J/\psi M$ decays

$$A(B_c^+ \rightarrow J/\psi M^+) \sim \int dx_1 dx_2 dx_3 b_1 db_1 b_2 db_2 b_3 db_3 \cdot \text{Tr} \left[C(t) \Phi_{B_c}(x_1, b_1) \Phi_M(x_2, b_2) \Phi_{J/\psi}(x_3, b_3) H(x_i, b_i, t) e^{-S(t)} \right] ,$$

Figure 3 Feynman diagrams for $B_c \rightarrow J/\psi M$ at leading order in the iPQCD formalism: (a) and (b) are the factorizable emission diagrams, and (c) and (d) are the nonfactorizable emission ones.

The factorization formulas for the decays $B_c \rightarrow J/\psi M$ could be found in the Appendix B of arXiv:2305.00713 explicitly.

RESULTS and DISCUSSIONS

A. $B_c \rightarrow J/\psi$ (P, V, a1)

◆ Branching fractions for $B_c \rightarrow J/\psi P$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+) = 1.17^{+0.31}_{-0.23} (\beta_{B_c})^{+0.08}_{-0.08} (f_M)^{+0.00}_{-0.00} (a_\pi) \times 10^{-3}, \quad 1.17^{+0.32}_{-0.24}$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi K^+) = 8.68^{+2.32}_{-1.73} (\beta_{B_c})^{+0.64}_{-0.62} (f_M)^{+0.66}_{-0.63} (a_K) \times 10^{-5}, \quad 8.68^{+2.50}_{-1.94}$$

- They are consistent generally with those already available in the literature within errors and particularly with those in the QCDF approach. Furthermore, they agree well with those in CCQM and LCSR presented very recently.

$$B_c^+ \rightarrow J/\psi \pi^+ \quad B_c^+ \rightarrow J/\psi K^+$$

$$0.101 \pm 0.02 \quad \% \quad 0.008 \pm 0.002 \quad \%$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+) = (0.136^{+0.002}_{-0.002})\%,$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi K^+) = (0.010^{+0.000}_{-0.000})\%,$$

Issadykov and Ivanov, arXiv:1804.00472

Cheng et al, arXiv:2107.08405

◆ Relative ratio,

$$R_{K/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.074_{-0.005}^{+0.006},$$

- Within errors, it is in good consistency with the latest measurement, and also with the naïve expectation and the very recent predictions in CCQM and LCSR.
- Dramatical cancelation occurs in the nonfactorizable emission diagrams under isospin limit.
- Slight deviation for $R_{K/\pi}$ between the iPQCD prediction and the naïve expectation is attributed to the SU(3)-flavor symmetry breaking effects appearing in the nonfactorizable emission amplitudes proportional to kaon DA at twist-2.
- As a byproduct, the above naïve expectation for the relative ratios between the branching fractions of Bc to other charmonia plus a kaon and a pion could also be anticipated.

◆ Branching fractions for $B_c \rightarrow J/\psi V$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi \rho^+) = 3.69_{-0.76}^{+1.02} (\beta_{B_c})_{-0.27}^{+0.28} (f_M)_{-0.00}^{+0.01} (a_\rho) \times 10^{-3}, \quad 3.69_{-0.81}^{+1.06}$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi K^{*+}) = 2.23_{-0.46}^{+0.62} (\beta_{B_c})_{-0.18}^{+0.20} (f_M)_{-0.01}^{+0.02} (a_{K^*}) \times 10^{-4}, \quad 2.23_{-0.49}^{+0.65}$$

- Evident discrepancies appear in lots of predictions with different approaches and models. The iPQCD predictions agree well with those in CCQM.

$$\text{Br}_{LC}(B_c \rightarrow J/\psi \rho) = 0.38\%,$$

$$\text{Br}_{QM}(B_c \rightarrow J/\psi \rho) = 0.44\%,$$

$$\text{Br}_{SR}(B_c \rightarrow J/\psi \rho) = 0.48\%.$$

Likhoded and Luchinsky, arXiv:0910.3089

$$B_c^+ \rightarrow J/\psi \rho^+ \\ 0.334 \pm 0.067 \%$$

$$B_c^+ \rightarrow J/\psi K^{*+} \\ 0.019 \pm 0.004 \%$$

Issadykov and Ivanov, arXiv:1804.00472

◆ Relative ratio,

$$R_{K^*/\rho}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi \rho^+)} = 0.060_{-0.002}^{+0.002},$$

- It roughly agrees with the value 0.066 anticipated by naïve factorization and is indeed close to the similar one in $B_c \rightarrow J/\psi P$.

$$R_{\rho/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \rho^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 3.15_{-0.10}^{+0.09}, \quad R_{K^*/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.19_{-0.01}^{+0.01}.$$

- They agree basically with those available in the literature within errors and are expected to be tested in the future measurements.

◆ Branching fraction for $B_c \rightarrow J/\psi a_1$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi a_1^+) = 5.90_{-1.24}^{+1.63} (\beta_{B_c})_{-0.64}^{+0.66} (f_M)_{-0.00}^{+0.00} (a_{a_1}) \times 10^{-3}, \quad 5.90_{-1.40}^{+1.76}$$

- The similar QCD behavior with ρ meson and a bit larger decay constant f_{a_1} lead to this larger branching fraction.
- By assuming the validity of narrow-width approximation and with the equal branching ratios of $a_1 \rightarrow \pi^+ \pi^- \pi^+$ and $a_1 \rightarrow \pi^+ \pi^0 \pi^0$ around 50%,

arXiv:0708.0050

$$\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)_{\text{iPQCD}} \equiv \mathcal{B}(B_c^+ \rightarrow J/\psi a_1^+) \cdot \mathcal{B}(a_1^+ \rightarrow \pi^+ \pi^- \pi^+) = 2.95_{-0.70}^{+0.88} \times 10^{-3},$$

➤ It is surprisingly well consistent with the predictions in the literature within errors.

$$\begin{aligned} \text{Br}_{LC} (B_c \rightarrow J/\psi + 3\pi) &= 0.52\%, \\ \text{Br}_{QM} (B_c \rightarrow J/\psi + 3\pi) &= 0.64\%, \\ \text{Br}_{SR} (B_c \rightarrow J/\psi + 3\pi) &= 0.77\%. \end{aligned}$$

Likhoded and Luchinsky,
arXiv:0910.3089

$$\text{Br}(B_c^+ \rightarrow J/\psi + \pi^+ \pi^- \pi^+) \simeq 0.3\%.$$

Rakitin and Koshkarev,
arXiv:0911.3287

$$B_c \rightarrow J/\psi + (3\pi)_{\text{ch}} \quad | \quad 0.39\% \quad | \quad 0.45\% \quad | \quad 0.14\%$$

Luchinsky, arXiv:1208.1398

◆ Relative ratio,

$$R_{3\pi/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)_{\text{iPQCD}}}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)_{\text{iPQCD}}} = 2.52_{-0.10}^{+0.05},$$

➤ It is well consistent with the measurements by LHCb and CMS, and the averaged value by HFLAV within errors.

◆ Additionally,

$$\mathcal{B}(a_1^+ \rightarrow K^+ K^- \pi^+)_{\text{iPQCD}} \equiv R_{2K\pi/\pi}^{\text{Exp}} \cdot \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi a_1^+)} \approx (10.5_{-1.9}^{+2.0})\%,$$

- The detection on this value would help understand the nature of a_1 .

$$\mathcal{B}(B_c^+ \rightarrow J/\psi K^+ K^- \pi^+)_{\text{iPQCD}} \equiv R_{2K\pi/3\pi}^{\text{Exp}} \cdot \mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+ \pi^- \pi^+)_{\text{iPQCD}} = 5.46_{-1.40}^{+1.68} \times 10^{-4} .$$

- It is roughly consistent with the predictions given in different form factors within a bit large errors.

0.081% and 0.03%

Luchinsky, arXiv:1307.0953

$$R_{a_1/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a_1^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 5.04_{-0.15}^{+0.10} ,$$

$$R_{a_1/\rho}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a_1^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \rho^+)} = 1.60_{-0.11}^{+0.10} ,$$

- Tests on these two ratios could help further understand the QCD behavior of a_1 .
- But, without individual decay rates, the F.E.A. dominated decays cannot help reveal the dynamics and constrain the shape parameter β_{B_c} .
- The explorations on the modes governed by large nonfactorizable decay amplitudes are of great necessity.

B. $B_c \rightarrow J/\psi b_1$ (S)

◆ Branching fraction for $B_c \rightarrow J/\psi b_1$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi b_1^+) = 7.93_{-1.83}^{+2.43} (\beta_{B_c})_{-0.89}^{+0.93} (f_M)_{-2.59}^{+3.09} (a_{b_1}) \times 10^{-4} \cdot 7.93_{-3.29}^{+4.04}$$

➤ The anti-symmetric QCD behavior of b_1 -meson DA at twist-2 and the nearly vanished decay constant $f_{b_1^+}$ result in a smaller branching fraction of $B_c \rightarrow J/\psi b_1$ than that of $B_c \rightarrow J/\psi a_1$.

◆ Relative ratio,

$$R_{b_1/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi b_1^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.68_{-0.22}^{+0.26},$$

➤ Its experimental measurements could provide useful hints to test the reliability of the adopted iPQCD formalism and phenomenologically constrain β_{B_c} .

$$R_{b_1/\rho}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi b_1^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \rho^+)} = 0.21_{-0.07}^{+0.09}.$$

- Tests on this ratio could provide information on the QCD behavior of b_1 meson.
- ◆ Different from $B_c \rightarrow J/\psi b_1$ with angular decomposition, the $B_c \rightarrow J/\psi S$ decays have only longitudinal contributions due to conservation of the angular momentum.
- ◆ The factorizable emission amplitudes are strongly suppressed due to the highly small vector decay constants, while the asymmetric QCD behavior of twist-2 DAs leads to large nonfactorizable emission contributions.
- ◆ The light scalars are considered as two-quark structure mesons. Two possible scenarios:
 - In S1, a_0 and κ are ground states, then $a_0(1450)$ and $K_0^*(1430)$ are the first excited states;
 - In S2, $a_0(1450)$ and $K_0^*(1430)$ are ground states, then a_0 and κ are the four-quark states.

◆ Branching fractions for $B_c \rightarrow J/\psi a_0$ and $J/\psi \kappa$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi a_0^+) = 5.98_{-1.39}^{+1.77} (\beta_{B_c})_{-0.78}^{+0.80} (f_M)_{-1.22}^{+1.31} (B_i) \times 10^{-4}, \quad 5.98_{-2.01}^{+2.34}$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi \kappa^+) = 1.31_{-0.36}^{+0.50} (\beta_{B_c})_{-0.18}^{+0.18} (f_M)_{-0.35}^{+0.41} (B_i) \times 10^{-5}, \quad 1.31_{-0.53}^{+0.67}$$

with relative ratios,

$$R_{a_0/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a_0^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.51_{-0.12}^{+0.13}, \quad R_{\kappa/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \kappa^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.011_{-0.004}^{+0.005},$$

➤ The future measurements on these results could help identify the $q\bar{q}$ components in a_0 and κ .

◆ Branching fractions for $B_c \rightarrow J/\psi a_0(1450)$ and $J/\psi K_0^*(1430)$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi a_0'^+) = \begin{cases} 6.39_{-1.56}^{+2.09} (\beta_{B_c})_{-1.37}^{+1.52} (f_M)_{-1.89}^{+2.19} (B_i) \times 10^{-4} \\ 2.20_{-0.54}^{+0.71} (\beta_{B_c})_{-0.48}^{+0.54} (f_M)_{-1.02}^{+1.37} (B_i) \times 10^{-4} \end{cases}, \quad \begin{matrix} 6.39_{-2.81}^{+3.39} \\ 2.20_{-1.25}^{+1.63} \end{matrix}$$

$$\mathcal{B}(B_c^+ \rightarrow J/\psi K_0^{*+}) = \begin{cases} 3.22_{-0.66}^{+0.81} (\beta_{B_c})_{-0.64}^{+0.74} (f_M)_{-0.35}^{+0.37} (B_i) \times 10^{-5} \\ 2.23_{-0.70}^{+0.87} (\beta_{B_c})_{-0.51}^{+0.55} (f_M)_{-0.45}^{+0.65} (B_i) \times 10^{-5} \end{cases}, \quad \begin{matrix} 3.22_{-0.98}^{+1.16} \\ 2.23_{-0.98}^{+1.22} \end{matrix}$$

with relative ratios,

$$R_{a'_0/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a'_0^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = \begin{cases} 0.55^{+0.19}_{-0.17} \\ 0.19^{+0.12}_{-0.09} \end{cases}, \quad R_{K_0^{*+}/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K_0^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = \begin{cases} 0.028^{+0.003}_{-0.003} \\ 0.019^{+0.006}_{-0.005} \end{cases}$$

- The experimental measurements on these values could test the reliability of the adopted iPQCD formalism, and further help constrain the shape parameter β_{B_c} .

$$R_{\kappa/a_0}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi \kappa^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi a_0^+)} = 0.022^{+0.002}_{-0.002}, \quad R_{K_0^{*+}/a'_0}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K_0^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi a'_0^+)} = \begin{cases} 0.050^{+0.014}_{-0.008} \\ 0.101^{+0.050}_{-0.022} \end{cases}$$

- The future examinations on these ratios could help understand the QCD dynamics of these light scalars, and further identify the preferred scenario.
- The theoretical errors are remarkably large due to much less constraints experimentally. Nevertheless, the $B_c \rightarrow J/\psi S$ decays can still provide good chances to understand the involved dynamics because of the limit of naïve factorization in such kinds of decays.

C. $B_c \rightarrow J/\psi T$

- ◆ The tensors cannot be produced via V, A, S, and P currents. Therefore, the factorizable contributions with T-emission in $B_c \rightarrow J/\psi T$ are forbidden intuitively.
- ◆ The branching fractions of $B_c \rightarrow J/\psi T$ are contributed purely by the nonfactorizable emission amplitudes. It means that $B_c \rightarrow J/\psi T$ must be explored theoretically going beyond naïve factorization.
- ◆ Branching fractions for $B_c \rightarrow J/\psi T$,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+) = 1.39_{-0.33}^{+0.45} (\beta_{B_c})_{-0.18}^{+0.19} (f_M) \times 10^{-4}, \quad 1.39_{-0.38}^{+0.49}$$
$$\mathcal{B}(B_c^+ \rightarrow J/\psi K_2^{*+}) = 9.05_{-2.22}^{+2.91} (\beta_{B_c})_{-0.98}^{+1.03} (f_M) \times 10^{-6}, \quad 9.05_{-2.43}^{+3.09}$$

- By assuming the equal branching ratios of $a_2^{+-} \rightarrow \pi^+ \pi^- \pi^+$ and $a_2^{+-} \rightarrow \pi^+ \pi^0 \pi^0$ and the validity of narrow-width approximation, with $\mathcal{B}(a_2 \rightarrow 3 \pi) = (70.1 \pm 2.7)\%$, an interesting branching fraction associated with relative ratio could be obtained as,

$$\mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+ (\rightarrow \pi^+ \pi^- \pi^+)) \equiv \mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+) \cdot \mathcal{B}(a_2^+ \rightarrow \pi^+ \pi^- \pi^+) = 0.49_{-0.14}^{+0.17} \times 10^{-4},$$

$$R_{3\pi/\pi}^{a_2} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+ (\rightarrow \pi^+ \pi^- \pi^+))}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.042_{-0.004}^{+0.002}.$$

- These two values await future examinations to support the iPQCD formalism in dealing with these types of Bc-meson decays.

◆ Relative ratios,

$$R_{a_2/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+)}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.12_{-0.01}^{+0.01}, \quad R_{K_2^*/\pi}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K_2^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)} = 0.008_{-0.001}^{+0.000},$$

- These ratios can help explore the Bc \rightarrow J/ ψ T decays at LHC, even CEPC in the future.

◆ One more interesting relative ratio,

$$R_{K_2^*/a_2}^{\text{Theo}} \equiv \frac{\mathcal{B}(B_c^+ \rightarrow J/\psi K_2^{*+})}{\mathcal{B}(B_c^+ \rightarrow J/\psi a_2^+)} = 0.065_{-0.002}^{+0.002}.$$

- It could be cleanly written as $(f_{K_2^*}/f_{a_2})^2 |V_{us}/V_{ud}|^2 \sim 0.066$ due to SU(3)-flavor symmetry in the T-meson leading-twist distribution amplitudes.
- It agrees perfectly with naïve expectation $R_{K^*/\rho}$ while is slightly larger than that in iPQCD, because of SU(3) symmetry breaking effects in nF.E.A destructively interfering with F.E.A in the $B_c \rightarrow J/\psi K^*$ mode.

SUMMARY and OUTLOOK

1. The relative ratios $R_{K/\pi}$, $R_{3\pi/\pi}$ and so on are highly consistent with data and most predictions, though no available individual decay rates experimentally. The iPQCD predictions await future tests at relevant experiments.

2. The branching fractions and their relative ratios of $B_c \rightarrow J/\psi S$, $J/\psi T$ and $J/\psi b1$, governed by nF.E.A, are predicted in iPQCD for the first time and will be confronted with future tests. The precise measurements could help constrain β_{B_c} to further understand (non)perturbative dynamics.

3. The model-independent ratio $R_{K2^*/a2}$ is obtained in iPQCD and is expected to shed light on the information of β_{B_c} promisingly.

4. Suggest our experimental colleagues to focus on the B_c -meson decays predominated by nF.E.A. that could help examine the reliability of iPQCD.

◆ Outlook

- To precisely determine β_{Bc} , one-loop QCD corrections to the Bc-meson wave function, correlated with productions and decays of the Bc meson is urgently demanded;
- To precisely study Bc decays to charm mesons, a new Sudakov factor is demanded due to the charm quark mass effects;
- To extend the iPQCD formalism to baryonic Bc-meson decays, new Sudakov factors for baryon are important to make the framework self-consistent;
-

Thanks for your attention!
