# THE HIGGS MECHANISM

# THE HIGGS MECHANISM

# HOW TO GIVE MASS TO PARTICLES?

- Imagine a particle interacting with a scalar field in CM:

$$L_{\text{CM}} = \frac{1}{2}m\dot{x}^2 - g\phi(t, x)$$

- Plugging it in the Euler-Lagrange equation we get:  $m\ddot{x} = -g\frac{\partial\phi(t, x)}{\partial x}$
- If we switch to the STR, the free particle Lagrangian becomes:

$$L_{\text{STR}} = -mc^2\sqrt{1 - \frac{\dot{x}^2}{c^2}}$$

- How can we couple it to a scalar field?

- Option  $L_{\text{STR}} = -[mc^2 + g\phi(t, x)]\sqrt{1 - \frac{\dot{x}^2}{c^2}}$  reduces to  $L_{\text{CM}}$  in the limit  $v \ll c$ .

- If we again plug it in the Euler-Lagrange equation, we get:

$$\frac{d}{dt} \frac{(m + g\phi(t, x))\dot{x}}{\sqrt{1 - \dot{x}^2/c^2}} = -g \frac{\partial\phi(t, x)}{\partial x} \sqrt{1 - \frac{\dot{x}^2}{c^2}}$$

- or in the limit of  $v \ll c$

$$\frac{d}{dt} [(m + g\phi(t, x))\dot{x}] = -g \frac{\partial\phi(t, x)}{\partial x}$$

- A very interesting and beautiful thing happens if the scalar field is constant  $\phi(t, x) = C$ :

$$(m + g\phi(t, x))\ddot{x} = 0$$

- A particle of mass  $m$  interacting with the constant scalar field  $\phi$  moves like a free particle of mass  $m + \phi$  !

# IT IS NOT THAT SIMPLE!

## Symmetries:

- Global Poincare
- Local  $SU(3) \otimes SU(2) \otimes U(1)$

**\*Simply adding the mass term in the Lagrangian completely destroys the symmetries and in turn laws of conservation!**

### Abstract

Results are presented from searches for the standard model Higgs boson in proton–proton collisions at  $\sqrt{s} = 7$  and 8 TeV in the Compact Muon Solenoid experiment at the LHC, using data samples corresponding to integrated luminosities of up to  $5.1 \text{ fb}^{-1}$  at 7 TeV and  $5.3 \text{ fb}^{-1}$  at 8 TeV. The search is performed in five decay modes:  $\gamma\gamma$ ,  $ZZ$ ,  $W^+W^-$ ,  $\tau^+\tau^-$ , and  $b\bar{b}$ . An excess of events is observed above the expected background, with a local significance of 5.0 standard deviations, at a mass near 125 GeV, signalling the production of a new particle. The expected significance for a standard model Higgs boson of that mass is 5.8 standard deviations. The excess is most significant in the two decay modes with the best mass resolution,  $\gamma\gamma$  and  $ZZ$ ; a fit to these signals gives a mass of  $125.3 \pm 0.4(\text{stat.}) \pm 0.5(\text{syst.}) \text{ GeV}$ . The decay to two photons indicates that the new particle is a boson with spin different from one.

### Abstract

A search for the Standard Model Higgs boson in proton–proton collisions with the ATLAS detector at the LHC is presented. The datasets used correspond to integrated luminosities of approximately  $4.8 \text{ fb}^{-1}$  collected at  $\sqrt{s} = 7 \text{ TeV}$  in 2011 and  $5.8 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$  in 2012. Individual searches in the channels  $H \rightarrow ZZ^{(*)} \rightarrow 4 \ell$ ,  $H \rightarrow \gamma\gamma$  and  $H \rightarrow WW^{(*)} \rightarrow e\nu\mu\nu$  in the 8 TeV data are combined with previously published results of searches for  $H \rightarrow ZZ^{(*)}$ ,  $WW^{(*)}$ ,  $b\bar{b}$  and  $\tau^+\tau^-$  in the 7 TeV data and results from improved analyses of the  $H \rightarrow ZZ^{(*)} \rightarrow 4 \ell$  and  $H \rightarrow \gamma\gamma$  channels in the 7 TeV data. Clear evidence for the production of a neutral boson with a measured mass of  $126.0 \pm 0.4 \text{ (stat)} \pm 0.4 \text{ (sys)} \text{ GeV}$  is presented. This observation, which has a significance of 5.9 standard deviations, corresponding to a background fluctuation probability of  $1.7 \times 10^{-9}$ , is compatible with the production and decay of the Standard Model Higgs boson.
