## The sensitivity and discovery potential of nEXO

Thursday 7 December 2023 17:00 (20 minutes)

Neutrinoless double beta decay  $(0\nu\beta\beta)$  is a hypothetical nuclear process which, if observed, would have farreaching implications in particle physics. Being a lepton number violating process, the observation of  $0\nu\beta\beta$  is direct evidence for physics beyond the Standard Model. In addition, it would prove that neutrinos are Majorana particles, and contribute to the determination of the neutrino mass scale. nEXO is a proposed next-generation experiment that will search for  $0\nu\beta\beta$  of 136Xe. nEXO plans to use a liquid xenon time projection chamber that employs 5 tonnes of xenon, isotopically enriched to 90% in Xe-136. Ionization electrons and scintillation photons will be detected by segmented anode tiles and silicon photomultipliers, respectively. These will enable event-by-event reconstruction of event energy, position, and topology which will be used in a multi-parameter analysis to search for  $0\nu\beta\beta$  events. The projected sensitivity of nEXO to the Xe-136  $0\nu\beta\beta$  half-life is  $1.35\times10^{\circ}28$  years after 10 years of data-taking. The nEXO project is being developed by a collaboration of 34 institutions from 9 countries. In this talk, an overview of nEXO will be presented followed by a description of the conceptual design.

## Name of collaboration or list of co-authors

nEXO Collaboration

**Primary author:** Prof. MACLELLAN, Ryan (University of Kentucky)

Presenter: Prof. MACLELLAN, Ryan (University of Kentucky)

Session Classification: Thursday afternoon
