PART I

~1950

- New particle discoveries : Strangeness emergence

1963

- Cabibbo Theory

θ_c : the Cabibbo angle

$$\begin{pmatrix} u \\ d_c \end{pmatrix} = \begin{pmatrix} u \\ d \cos \theta_c + s \sin \theta_c \end{pmatrix}$$

~1970

- Neutral current in neutrino interaction : Z0 emergence (direct discovery in 1983 !)

~1970

- Absence of Flavour Changing Neutral Current (FCNC) : charm emergence

~1970

- Cabibbo Matrix

$$(\bar{u}, \bar{c}) \gamma^\mu (1 - \gamma_5) V \begin{pmatrix} d \\ s \end{pmatrix}$$

$$V = \begin{pmatrix} \cos \theta_c & \sin \theta_c \\ -\sin \theta_c & \cos \theta_c \end{pmatrix}$$

1974

- Discovery of J/Psi

Fundamental role of strange particles in the development of flavour physics. I use them to introduce flavour physics

To show where I start from...

~1950

The concept of flavour : strangeness discovery

In these lectures I'll have an historical approach

The Strangeness : the begin of a new era...not ended yet

~1947 : discovery of new particles (on cosmic rays)

– K (~ 500 MeV) Λ (~ 1100 MeV)

Why are these particles strange ?

- They are produced (always in pair) as copiously as the π
- Their lifetime is $\sim 10^{-10}$ s !

Production through strong interaction

Decay through weak interaction

There should be a reason to inhibit the decay through strong interactions.....

→ Introduction of a new quantum number

- Conserved in strong interaction processes
- Not conserved on weak interaction processes

The strangeness

(additive quantum number)

Pais intuition (1952)

V - Particle

«Kink» in the detector

Bubbles Chamber ~1947

Tracks from Λ

Produced in pair

1955 Walker *et al* (Berkeley)

Several new “strange” particles were discovered. They were decaying in cascade to other strange particles.

Experimentally, from the observation of the decay of particles as the Ξ^\pm it comes out that, the strangeness is an *additive quantum number*

particle	S
p, n, π^\pm , π^0	0
Λ , Σ^\pm , Σ^0	-1
Ξ^\pm , Ξ^0	-2
K^0 , K^+	+1
\bar{K}^0 , K^-	-1

Why additive?

Exp. τ_Ξ is typical of weak interaction

Analogy with the parity ± 1

If multiplicatif

$$\Xi \rightarrow \Lambda \pi$$

-1	-1	1
----	----	---

OK \Rightarrow Strong int. possible

If additif

-2	-1	0
----	----	---

$\neq \Rightarrow$ weak interaction

PHYSICAL REVIEW

A journal of experimental and theoretical physics established by E. L. Nichols in 1893

SECOND SERIES, VOL. 86, No. 5

JUNE 1, 1952

“V particle”: particles that are produced in pairs and thus leaves a ‘v’ trail in a bubble chamber picture

Some Remarks on the V-Particles*

A. PAIS

Institute for Advanced Study, Princeton, New Jersey

(Received January 22, 1952)

It is qualitatively investigated whether the abundance of V-particle production can be reconciled with their long lifetime by using only interactions of a conventional structure. This is possible, provided a V-particle is produced together with another heavy unstable particle (Sec. II). Two distinct groups of interactions are needed: for one, the coupling is strong (II); for the other, it is very weak (III). Two kinds of V-particles are considered, Fermions of mass $\sim 2200m$ and Bosons ($\sim 800m$). The arguments are somewhat different, according to whether the latter are nonpseudoscalar (III) or pseudoscalar (V). The competition with processes involving μ -mesons is discussed (IV). Possible connections with the τ -meson are commented on in Sec. V. The preliminary nature of the present analysis is stressed (VI).

Observations:

1. High production cross-section
2. Long lifetime

Conclusion:

must always be produced in pairs!

Details: create a new quantum number, “strangeness” which is conserved by the production process (pair production) however, the decay must violate “strangeness” if only weak force is “strangeness violating” then it is responsible for the decay process

hence (relatively) long lifetime...

Strangeness and the birth of Flavour Physics

The strangeness is nothing else than the quantum number associated to a new quark : **the strange quark s**

How do we see the decay of a strange particle ?

But there was a further question :

PUZZLEING about lifetimes.

The lifetime of Λ was measured of $\sim 2 \times 10^{-10}$ s, same for charged kaon was measured $\sim 1.2 \times 10^{-8}$

How it compared with for instance with muon lifetime $\tau(\mu) \sim 10^{-6}$ s (or pion) ?

$$\Gamma_i / \Gamma_{\text{tot}} = \text{Br}_i \rightarrow \Gamma_i = \text{Br}_i / \tau$$

$$\frac{\Gamma(K \rightarrow \mu \nu)}{\Gamma(\pi \rightarrow \mu \nu)} = \frac{\tau(\pi)}{\tau(K)} \frac{\text{BR}(K^+ \rightarrow \mu^+ \nu)}{\text{BR}(\pi^+ \rightarrow \mu^+ \nu)} = \underbrace{(\sim 0.63)}_{\text{coupling}} \cdot \underbrace{\left[\frac{m_K}{m_\pi} \frac{1 - (m_\mu/m_K)^2}{1 - (m_\mu/m_\pi)^2} \right]^2}_{18} \quad \leftarrow \text{Phase space}$$

$$\tau(\pi) = 2.6 \times 10^{-8} \text{ s}$$

$$\tau(K) = 0.035 \times \tau(\pi) = 9 \times 10^{-10} \text{ s}$$

BUT EXPERIMENTALLY $\tau(K) = 1.2 \times 10^{-8} \text{ s}$

SO the lifetime of the K is slower than expected

- There is a coupling which is slowing down the decay of the K

1963 $\Delta S=1$ vs $\Delta S=0$ Cabibbo theory

The quarks d e s involved in weak processes are « rotated » by an angle

Couplings : $u d \quad G_F \cos\theta_c$

θ_c : the Cabibbo angle

$$\begin{pmatrix} u \\ d_c \end{pmatrix} = \begin{pmatrix} u \\ d \cos\theta_c + s \sin\theta_c \end{pmatrix}$$

$u s \quad G_F \sin\theta_c$

$\Delta S=1$

$\cos\theta_c$ or $\sin\theta_c$

UNITARY SYMMETRY AND LEPTONIC DECAYS

Nicola Cabibbo
CERN, Geneva, Switzerland
(Received 29 April 1963)

To determine θ , let us compare the rates for $K^+ \rightarrow \mu^+ + \nu$ and $\pi^+ \rightarrow \mu^+ + \nu$; we find

$$\Gamma(K^+ \rightarrow \mu\nu) / \Gamma(\pi^+ \rightarrow \mu\nu) = \tan^2\theta \frac{M_K^2 (1 - M_\mu^2/M_K^2)^2 / M_K^2}{M_\pi^2 (1 - M_\mu^2/M_\pi^2)^2} \quad (3)$$

From the experimental data, we then get^{5,6}

$$\theta = 0.257. \quad (4)$$

For an independent determination of θ , let us consider $K^+ \rightarrow \pi^0 + e^+ + \nu$. The matrix element for this process can be connected to that for $\pi^+ \rightarrow \pi^0 + e^+ + \nu$, known from the conserved vector-current hypothesis (2nd assumption). From the rate⁶ for $K^+ \rightarrow \pi^0 + e^+ + \nu$, we get

$$\theta = 0.26. \quad (5)$$

The two determinations coincide within experimental errors; in the following we use $\theta = 0.26$.

$$G_F^2 \sin^2\theta_c$$

$$K^- \rightarrow \pi^0 e^- \nu_e$$

Cabibbo Theory : The quarks d e s involved in weak processes are « rotated » by an angle

θ_c : the Cabibbo angle

$$\begin{pmatrix} u \\ d_c \end{pmatrix} = \begin{pmatrix} u \\ d \cos \theta_c + s \sin \theta_c \end{pmatrix}$$

Couplings : $u d \quad G_F \cos \theta_c$ $u s \quad G_F \sin \theta_c$

$\Delta S=0$

$\Delta S=1$

Many measurements

explained with :

Weak interaction among quarks
Non universal

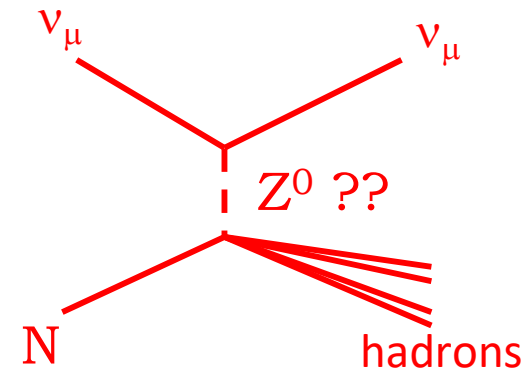

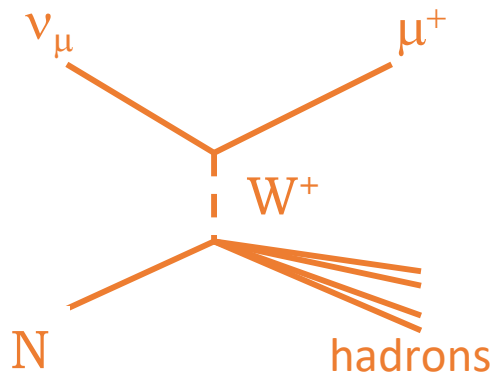

The years '70

DISCOVERY OF WEAK CURRENTS in NEUTRINO INTERACTIONS

Schematically : neutral current and charged current involving neutrino

- $\nu_\mu N \rightarrow \mu X$ charged current
- $\nu_\mu N \rightarrow \nu_\mu X$ neutral current

Gargamelle was a bubble chamber at CERN designed to detect neutrinos. It operated from 1970 to 1976 with a muon-neutrino beam produced by the CERN [Proton Synchrotron](#), before moving to the [Super Proton Synchrotron](#) (SPS) until 1979.

Gargamelle was 4.8 metres long and 2 metres in diameter. It weighed 1000 tonnes and held nearly 12 cubic metres of heavy-liquid freon (CF₃Br).

A typical neutrino event as observed in
the Big European Bubble Chamber (BEBC)
filled with neon
(CERN 450 GeV Super Proton Synchrotron (SPS))

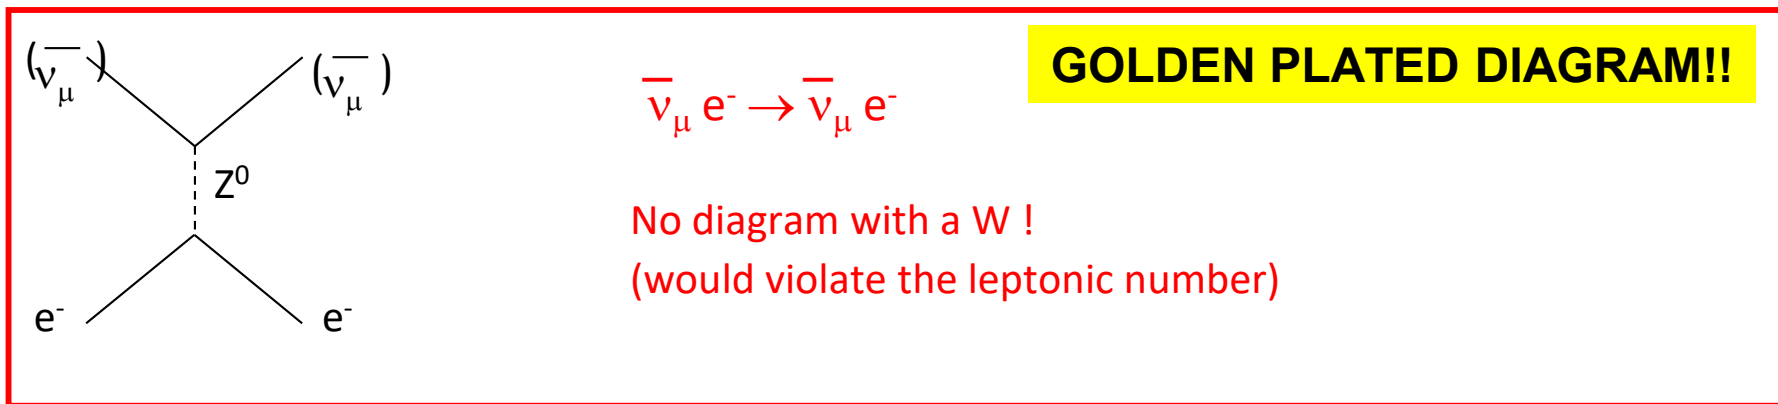

The muon can be seen on the left.
It has been tagged by an external muon
identifier. The many-particle hadron shower is
visible on the right.

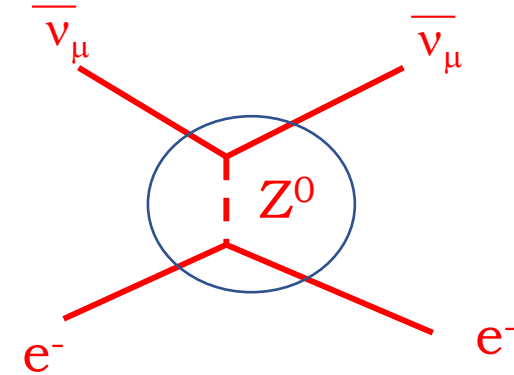

hadronic neutral current event, where the interaction of the neutrino coming from the left produces three secondary particles, all clearly identifiable as hadrons, as they interact with other nuclei in the liquid. There is no charged lepton (muon or electron).

MORE diagrams concerning neutrino interaction with electrons

Gargamelle : Phys. Lett. B46, 138-140 (1973)

Over a total of 1.4 million pictures:
3 events (data taking : 2 ans)

GOLDEN PLATED EVENT
Almost background free !!

The electron is projected forward with an energy of 400 MeV at an angle of

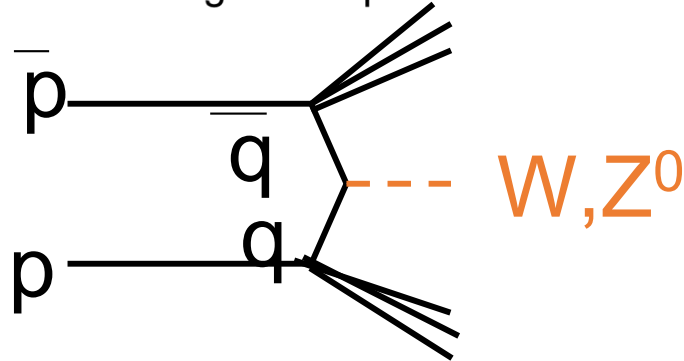

$1.5 \pm 1.5^\circ$ to the beam, entering from the right.

Kinematical analysis : direction close from the direction of the incoming ν beam

A little jump in History !

The Z⁰ was really discovered 15 year later
THE DISCOVERY OF W⁺⁻ and Z⁰ bosons
at SPS at CERN by UA1 and UA2 Coll.

- CERN 1983
- Proton -- anti-proton collider ($Spp\bar{S}$)
- Centre-of-mass energy 540 GeV
- Innovative cooling of anti-proton beam

$$p p \rightarrow W^+ X^-$$

$$p p \rightarrow Z^0 X^0$$

Antiproton Accumulator in 1980.

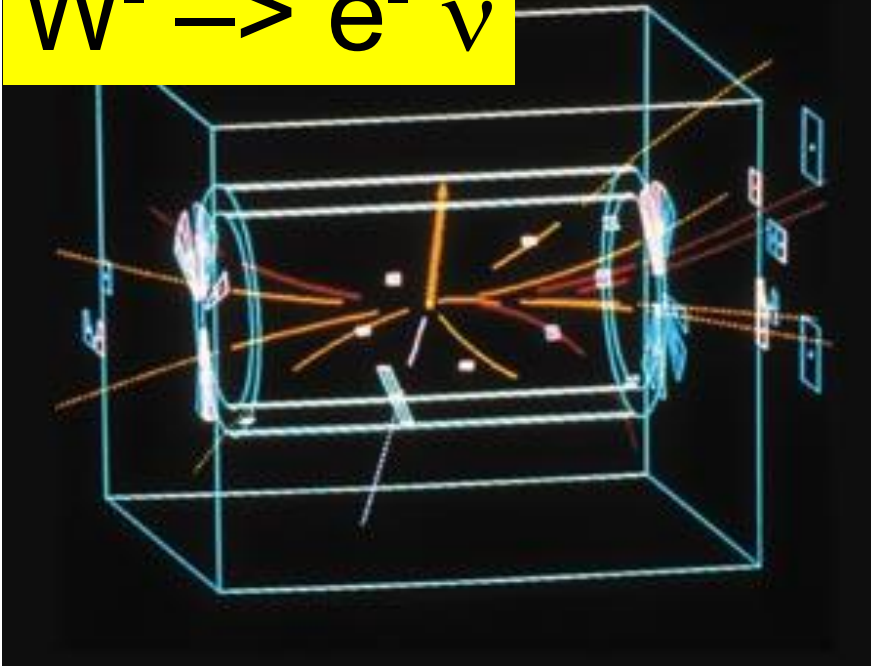

$$u\bar{d} \rightarrow W^+$$

$$u\bar{u}, d\bar{d} \rightarrow Z^0$$

$$W^+ \rightarrow l^+ \nu_l$$

$$Z^0 \rightarrow l^+ l^-$$

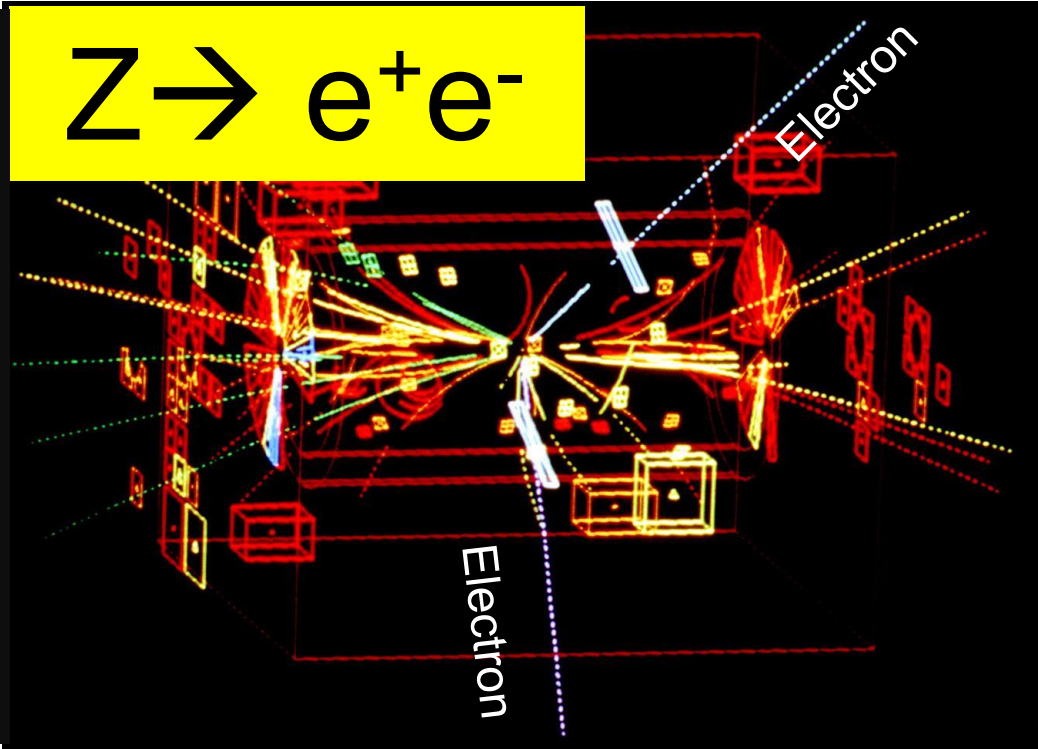

$$W^- \rightarrow e^- \nu$$

The decay of a W particle in the UA1 detector

showing the track of the high-energy electron towards the bottom. The yellow arrow marks the direction of the missing transverse energy and hence the path of the unseen neutrino.

$$Z \rightarrow e^+ e^-$$

One of the first Z particles observed in UA1.

The two white tracks (towards the top right and almost directly downwards) reveal the Z's decay into an electron-positron pair that deposit their energy in the electromagnetic calorimeter.

Z⁰ discovery paper

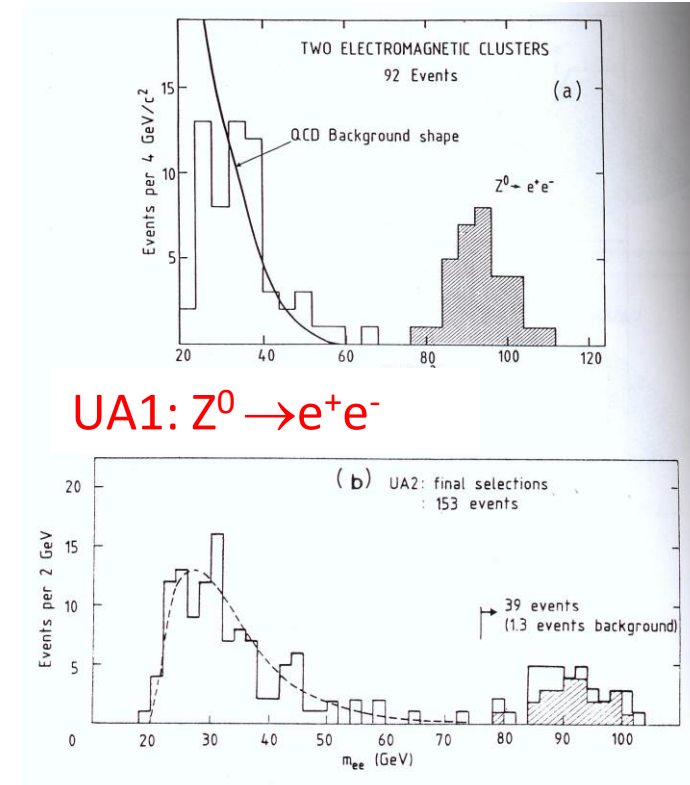

UA1 collaboration

Received 6 June 1983

We report the observation of four electron-positron pairs and one muon pair which have the signature of a two-body decay of a particle of mass $\sim 95 \text{ GeV}/c^2$. These events fit well the hypothesis that they are produced by the process $p + p \rightarrow Z^0 + X$ (with $Z^0 \rightarrow \ell^+ + \ell^-$), where Z^0 is the Intermediate Vector Boson postulated by the electroweak theories as the mediator of weak neutral currents.

And later !

UA1: $Z^0 \rightarrow e^+e^-$

UA2: $Z^0 \rightarrow e^+e^-$

SM PREDICTION !

$$M_W = \left(\frac{\sqrt{2} g^2}{8G_F} \right)^{1/2} = \left(\frac{\sqrt{2} 4\pi\alpha}{8G_F \sin^2 \theta_W} \right)^{1/2}$$
$$= \left(\frac{\pi\alpha}{\sqrt{2}G_F} \right)^{1/2} \frac{1}{\sin \theta_W} = \frac{37.28}{\sin \theta_W} [\text{GeV}]$$

$M_W \sim 78 \text{ GeV}$

$$M_Z = \frac{M_W}{\cos \theta_W}$$

$$M_Z \sim 90 \text{ GeV}$$

MESUREMENTS!

And the first mass measurements of W^\pm, Z^0

$$M_W = 81 \pm 5 \text{ GeV}$$

$$M_Z = 95.2 \pm 2.5 \text{ GeV}/c^2 \text{ (UA1)}$$
$$= 91.9 \pm 1.9 \text{ GeV}/c^2 \text{ (UA2)}$$

Absence of FCNC.

The neutral current changing the strangeness ($\Delta S=1$) not observed

BUT Z^0 EXISTS...1973

DISCOVERY of the Neutral current.

Explained with a neutral weak boson

BACK TO THE CABIBBO THEORY

→ “predicts” flavour changing neutral transition : sd

$$u\bar{u} + d\bar{d} \cos^2 \theta_c + s\bar{s} \sin^2 \theta_c + (s\bar{d} + \bar{s}d) \cos \theta_c \sin \theta_c$$

$$g_{aa} = 0$$

$$g_{ud} = (g / \sqrt{2}) \cos \vartheta_C$$

$$g_{us} = (g / \sqrt{2}) \sin \vartheta_C$$

More formally. If we write the weak charged current

$$j_\mu^{\text{weak}} = g_{ab} \bar{q}_a \gamma_\mu \frac{(1-\gamma^5)}{2} q_b = \bar{q}_{aL} \gamma_\mu q_{bL}$$

$$q_L = \begin{pmatrix} u \\ d \cos \vartheta_C + s \sin \vartheta_C \end{pmatrix}_L$$

$$j_\mu^+ = (g / \sqrt{2}) (\bar{u}, \bar{d} \cos \vartheta_C + \bar{s} \cos \vartheta_C) \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} u \\ d \cos \vartheta_C + s \sin \vartheta_C \end{pmatrix} =$$

$$= (g / \sqrt{2}) \bar{u} d \cos \vartheta_C + (g / \sqrt{2}) \bar{u} s \sin \vartheta_C$$

$$j_\mu^+ = \bar{q}_L \sigma_+ q_L \quad ; \quad \sigma_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$

The interaction comes from a gauge group. From the previous page it seems to be clear that for the weak interactions the group is the weak isospin. σ_{+-} are the matrices which increase(decrease) of one unity the weak isospin. But to form an algebra we also need σ_3

$$j_\mu^0 = g(\bar{u}, \bar{d}_C) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} u \\ d_C \end{pmatrix} =$$

$$= u\bar{u} + d\bar{d} \cos^2 \theta_c + s\bar{s} \sin^2 \theta_c + (s\bar{d} + \bar{d}s) \cos \theta_c \sin \theta_c$$

FCNC

FCNC : The GIM Mechanism (1970)

..Or the « charm discovery » by FCNC in Kaon system

1969-70 Glashow, Iliopoulos, Maiani (GIM) proposed a solution to the $K^0 \rightarrow \mu^+ \mu^-$ rate puzzle.

1st
O
r
d
e
r

The branching fraction for $K^0 \rightarrow \mu^+ \mu^-$ expected to be small as the first order diagram is forbidden

$$\frac{BR(K^0 \rightarrow \mu^+ \mu^-)}{BR(K^+ \rightarrow \mu^+ \nu_\mu)} = \frac{7 \times 10^{-9}}{0.64} \approx 10^{-8}$$

$$(m_c^2 - m_u^2) / m_W^2 = O(10^{-4})$$

2nd
O
r
d
e
r

Prediction of the charm quark with mass ~ 1.5 GeV !

Directly observed in 1973

With only u quark there is an ultraviolet divergence

These two diagrams cancel out the divergence

More details

It remains a non zero contribution (which is infrared divergent) for momentum lower than the mc , which does not cancel out. The amount of cancellation depends on the mass of the new quark

$$\approx (m_c^2 - m_u^2) \cos^2 \theta_C \sin^2 \theta_C$$

For $m_c = m_u$ It would be $BR(K^0 \rightarrow \mu^+ \mu^-) = 0$

A quark mass of $\approx 1.5 \text{ GeV}$ is necessary to get good agreement with the experimental data.

First “evidence” for Charm quark! and the fact that m_c is such that was not yet observed...

Weak Interactions with Lepton-Hadron Symmetry*

S. L. GLASHOW, J. ILIOPOULOS, AND L. MAIANI†

Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts 02139

(Received 5 March 1970)

We propose a model of weak interactions in which the currents are constructed out of four basic quark fields and interact with a charged massive vector boson. We show, to all orders in perturbation theory, that the leading divergences do not violate any strong-interaction symmetry and the next to the leading divergences respect all observed weak-interaction selection rules. The model features a remarkable symmetry between leptons and quarks. The extension of our model to a complete Yang-Mills theory is discussed.

BACK TO THE CABIBBO THEORY → predicts flavour changing neutral transition : sd

$$u\bar{u} + d\bar{d} \cos^2 \theta_c + s\bar{s} \sin^2 \theta_c + (\bar{s}d + \bar{d}s) \cos \theta_c \sin \theta_c \longrightarrow$$

1970 : Glashow, Iliopoulos et Maiani (GIM) proposed the introduction of **a fourth quark : the quark c (of charge 2/3)** :

$$\begin{pmatrix} c \\ s_c \end{pmatrix} = \begin{pmatrix} c \\ s \cos \theta_c - d \sin \theta_c \end{pmatrix}$$

Term added to the neutral coupling
↙

$$c\bar{c} + s\bar{s} \cos^2 \theta_c + d\bar{d} \sin^2 \theta_c - (\bar{s}d + \bar{d}s) \cos \theta_c \sin \theta_c$$

$$\longrightarrow u\bar{u} + c\bar{c} + (d\bar{d} + s\bar{s}) \cos^2 \theta_c + (d\bar{d} + s\bar{s}) \sin^2 \theta_c = u\bar{u} + c\bar{c} + d\bar{d} + s\bar{s}$$

1) Strange particles have a longer lifetime than expected

→ introduction of Cabibbo theory.

2) The neutral current does not change flavour : absence of FCNC and the rareness of the $K_L \rightarrow \mu\mu$

→ prediction of the existence of the charm quark !

The interaction comes from a gauge group. From the previous page it seems to be clear that for the weak interactions the group is the weak isospin. σ_{+-} are the matrices which increase(decrease) of one unity the weak isospin. But to form an algebra we also need σ_3

$$j_\mu^0 = g(\bar{u}, \bar{d}_C) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} u \\ d_C \end{pmatrix} =$$

$$= u\bar{u} + d\bar{d} \cos^2 \theta_c + s\bar{s} \sin^2 \theta_c + (s\bar{d} + \bar{d}s) \cos \theta_c \sin \theta_c \quad \text{FCNC}$$

introducing $\begin{pmatrix} c \\ s_C = -d \sin \vartheta_C + s \cos \vartheta_C \end{pmatrix}_L$

Absence of FCNC

$$j_\mu^0 = g(\bar{u}, \bar{d}_C) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} u \\ d_C \end{pmatrix} + g(\bar{c}, \bar{s}_C) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} c \\ s_C \end{pmatrix} = u\bar{u} + d\bar{d} + s\bar{s} + c\bar{c}$$

$$j_\mu^0 = \bar{q}_L \sigma_3 q_L \quad ; \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

adding the charm in the charged currents

$$q = \begin{pmatrix} c \\ -d \sin \vartheta_c + s \cos \vartheta_c \end{pmatrix}$$

$$\begin{aligned} j_\mu^+ &= (g / \sqrt{2})(\bar{c}, -\bar{d} \sin \vartheta_c + \bar{s} \cos \vartheta_c) \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} c \\ -d \sin \vartheta_c + s \cos \vartheta_c \end{pmatrix} = \\ &= -(g / \sqrt{2})\bar{c}d \sin \vartheta_c + (g / \sqrt{2})\bar{c}\bar{s} \cos \vartheta_c \end{aligned}$$

$$j_\mu^+ = g / \sqrt{2}(\bar{u}, \bar{d}_c) \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} u \\ d_c \end{pmatrix} + g / \sqrt{2}(\bar{c}, \bar{s}_c) \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} c \\ s_c \end{pmatrix}$$

$$\rightarrow \begin{pmatrix} d_c \\ s_c \end{pmatrix} = V \begin{pmatrix} d \\ s \end{pmatrix} \quad \text{with} \quad V = \begin{pmatrix} \cos \theta_c & \sin \theta_c \\ -\sin \theta_c & \cos \theta_c \end{pmatrix}$$

$$(\bar{u}, \bar{c}) \gamma^\mu (1 - \gamma_5) V \begin{pmatrix} d \\ s \end{pmatrix}$$

$$V = \begin{pmatrix} \cos \theta_c & \sin \theta_c \\ -\sin \theta_c & \cos \theta_c \end{pmatrix}$$

Cabibbo Matrix

$$(\bar{u}, \bar{c}) \gamma^\mu (1 - \gamma_5) V \begin{pmatrix} d \\ s \end{pmatrix}$$

$$\begin{pmatrix} d_c \\ s_c \end{pmatrix} = V \begin{pmatrix} d \\ s \end{pmatrix} \quad V = \begin{pmatrix} \cos \theta_c & \sin \theta_c \\ -\sin \theta_c & \cos \theta_c \end{pmatrix}$$

neutron decay $u\bar{d} \sim G_F^2 \cos^2 \theta_c \sim G_F^2$

One parameter θ_c explains many phenomena

Important CONCLUSION

CONTRARY TO THE LEPTON SECTOR

The charged current coupling for quarks is not anymore universal

and this is codified in the **Cabibbo** matrix.

The neutral currents stay universal
we do not need extra parameters for their complete description

and this is completely included and comes out « naturally » from the Standard Model

We are still in a 2 X 2 world
made by
u, d, s, c quarks....
