Anatomy of precision calculations

- Perturbation theory expansion
 - scattering amplitudes for real and virtual corrections
 - subtraction scheme to extract and cancel singular configurations
 - universal anomalous dimensions for resummation
 - DGLAP evolution of parton distributions
 - soft-gluon resummation
 - resummation of large logarithms: p_T , N-jettiness, R ,
- Require (ideally analytic) computation of loop and phase space integrals

Multi-loop integrals

- Calculation of loop or phase space integrals

- phase space: cut loop integral
- expressed in generic loop integrals (here: two-loop)

$$I_{t,r,s}(p_1, \dots, p_n) = \int \frac{d^d k}{(2\pi)^d} \frac{d^d l}{(2\pi)^d} \frac{1}{D_1^{m_1} \dots D_t^{m_t}} S_1^{n_1} \dots S_q^{n_q}$$

- Two challenges

- algebraic complexity
 - reduce large number of loop integrals to smaller set of master integrals
- analytic complexity
 - evaluate master integrals (analytically or numerically)

Multi-loop integrals

- Reduction to master integrals: integration-by-part (IBP) equations

$$\int \frac{d^d k}{(2\pi)^d} \frac{d^d l}{(2\pi)^d} \frac{\partial}{\partial a^\mu} [b^\mu f(k, l, p_i)] = 0 \quad \text{with } a^\mu = k^\mu, l^\mu; b^\mu = k^\mu, l^\mu, p_i^\mu$$

- yield large system of linear relations among integrals (up to millions of equations)
- Method of solution
 - closed form
 - iterative with lexicographic ordering (Laporta algorithm: Reduze, FIRE, Kira, LiteRed,...)
- Result
 - generic integrals as linear combinations of a small number of master integrals

Multi-loop integrals

- Evaluation of master integrals
 - integrals are typically IR and/or UV divergent
- Direct numerical evaluation: sector decomposition (T.Binoth, G.Heinrich)
 - Partition of integration space into sectors of non-overlapping singularities
 - Laurent expansion of integrand

$$(1-z)^{-1-\epsilon} = -\frac{1}{\epsilon} \delta(1-z) + \sum_n \frac{(-\epsilon)^n}{n!} \left(\frac{\ln^n(1-z)}{1-z} \right)_+$$

- Numerical sector integrals: pySecDec, FIESTA
- Direct analytical evaluation: Mellin-Barnes, Feynman parameters
- Indirect analytical evaluation: differential equations

Multi-loop integrals

- Differential equations for master integrals (A.Kotikov; E. Remiddi, TG)
 - differentiate integrand with respect to masses or momenta
 - apply IBP identities

$$\begin{aligned}
 s_{123} \frac{\partial}{\partial s_{123}} \text{[Diagram: Circle with vertical line, momenta } p_{123}, p_{12}, p_3] &= \frac{d-4}{2} \frac{2s_{123} - s_{12}}{s_{123} - s_{12}} \text{[Diagram: Circle with vertical line, momenta } p_{123}, p_{12}, p_3] \\
 &\quad - \frac{3d-8}{2} \frac{1}{s_{123} - s_{12}} \text{[Diagram: Circle with horizontal line, momentum } p_{12}], \\
 s_{12} \frac{\partial}{\partial s_{12}} \text{[Diagram: Circle with vertical line, momenta } p_{123}, p_{12}, p_3] &= -\frac{d-4}{2} \frac{s_{12}}{s_{123} - s_{12}} \text{[Diagram: Circle with vertical line, momenta } p_{123}, p_{12}, p_3] \\
 &\quad + \frac{3d-8}{2} \frac{1}{s_{123} - s_{12}} \text{[Diagram: Circle with horizontal line, momentum } p_{12}].
 \end{aligned}$$

- integrate differential equations and match boundary conditions

Multi-loop integrals

- Systematic solution of DE

- d-log form (J. Henn)
- alphabet of process (letters = denominators)
- iterated integrals
- solutions: generalized polylogarithms (GPL)

$$G(w_1, \dots, w_n; z) = \int_0^z \frac{dt}{t - w_1} G(w_2, \dots, w_n; t)$$

- Requires

- derivation of differential equations: IBPs
- analytic expression for NxN matrix of differential equations for N masters
- optimized choice of master integrals: decoupling, diagonalization

$$s_{123} \frac{\partial}{\partial s_{123}} \left(\text{Diagram 1} \right) = \frac{d-4}{2} \frac{2s_{123} - s_{12}}{s_{123} - s_{12}} \left(\text{Diagram 1} \right) - \frac{3d-8}{2} \frac{1}{s_{123} - s_{12}} \left(\text{Diagram 2} \right),$$

$$s_{12} \frac{\partial}{\partial s_{12}} \left(\text{Diagram 1} \right) = -\frac{d-4}{2} \frac{s_{12}}{s_{123} - s_{12}} \left(\text{Diagram 1} \right) + \frac{3d-8}{2} \frac{1}{s_{123} - s_{12}} \left(\text{Diagram 2} \right).$$

Multi-loop integrals in practise

- Main bottleneck: IBP equations

$$I_{t,r,s}(p_1, \dots, p_n) = \int \frac{d^d k}{(2\pi)^d} \frac{d^d l}{(2\pi)^d} \frac{1}{D_1^{m_1} \dots D_t^{m_t}} S_1^{n_1} \dots S_q^{n_q}$$

- t: number of different propagators
- r: mass dimension of denominator ($r \geq t$)
- s: mass dimension of numerator
- Examples at current frontier: $10^{6..7}$ integrals to $10^{2..3}$ master integrals
 - three-loop 2 \rightarrow 2 amplitudes: $4 \leq t \leq 10, t \leq r \leq 10, s \leq 6$
 - four-loop OME for splitting functions: $5 \leq t \leq 15, t \leq r \leq 15, s \leq 6$
 - differential equations for master integrals: same (t,r), typically $s \leq 2$
- Combinatorial explosion of IBP system size

Multi-loop integrals in practise

- Classical approach to IBP solutions: Laporta algorithm
 - IBP codes (Reduze, FIRE, Kira, LiteRed,...) use MPI for parallelization
 - run typically on multi-core machines with ~TB of RAM
 - distribute subsystems on different threads
 - limitations: memory usage per thread, interconnection of subsystems
- Algebraic complexity
 - critically depends on number of scales (space-time dimension d , masses, invariants)
 - large-scale algebraic simplifications at intermediate stages or as final step (polynomial arithmetic, using external tools: Fermat, Ginac, Symbolica)
 - size of results (reduction tables, after simplification): can be TBs, insertion time-consuming

Multi-loop integrals in practise

- **Improvement to IBP reduction: syzygy equations** (J.Gluza, D.Kosower, K.Larsen)
 - taming combinatorial growth: select IBP seed equations to always have $r = t$
 - must derive syzygy equations for each integral topology: poor automation
- **Finite field methods** (A. von Manteuffel, R.Schabinger; T. Peraro)
 - solve IBP system for multiple integer values of d , masses and invariants (or subset)
 - perform integer arithmetic modulo some large number
 - full workflow can be done on finite field
 - reconstruct all rational coefficients in solution (FiniteFlow, Kira, FinRed)
- **Challenges with finite field methods**
 - point of reconstruction: IBP tables, integral coefficients, GPL coefficients
 - number of evaluations required for reconstruction and validation
 - inversion of rational matrices as task: could profit from novel computer architectures

Multi-loop integrals in practise

- Limitation of algebraic approaches: number of mass scales (internal masses)
 - Complexity of IBPs and DEs (size of alphabet \sim number of possible kinematical cuts)
 - IBP reduction often not feasible, neither for amplitude nor for differential equation
- Numerical approach to IBP
 - IBP reduction and derivation of DE for each set of fixed numerical masses and kinematics
 - repeated for each phase space point (timing)
 - for symbolic d , truncated to finite terms in $\varepsilon = (4-d)/2$
 - integer arithmetic
- Numerical approach to high-precision solutions to DE
 - solution by asymptotic series: DiffExp, SeaSyde
(M.Hidding; T.Armadillo, R. Bonciani, S. Devoto, N. Rana, A. Vicini)
 - differential equations in complex mass parameter (Feynman $+i\delta$): AMFlow (X. Lui, Y.Q. Ma)

Summary

Main bottleneck in calculation of loop amplitudes: solution of IBPs

- express loop amplitudes as linear combination of master integrals
- prerequisite for computation of master integrals from differential equations
- Task: solve large systems of linear equations with rational coefficients

Approaches

- symbolic solution: Laporta algorithm (+ syzygy) (+ finite field reconstruction)
- numerical solution: IBP and DE solution for each phase space point

Computing challenges

- problem size often memory and storage limited
- hardware solutions for large linear systems
- parallelization at different stages
