The NEWS-G dark matter experiment: Shifting from LSM to SNOLAB data

Jean-Marie Coquillat

CAP conference, London ON

May 27th, 2024
Dark matter theory

• Dark matter (DM) evidence:
  ◦ First Zwicky (1933): Visible mass of galaxies much lower than expectation from virial theorem.
  ◦ Rotation curves have velocities stay higher than expected from Kepler’s 3rd law.
  ◦ Fits on the CMB show 85% of the Universe’s mass as non-baryonic matter
  ◦ Gravitational lensing shows the actual mass distribution of galaxies. Most of the Bullet cluster’s mass is invisible and less interacting.
Low mass WIMP search motivation

Given the absence of canonical WIMPs, there is motivation to look at the parameter space left at lower masses (\(\sim 0.1\) - 1 GeV) for WIMP-like dark matter candidates.

arXiv:2104.07634 [hep-ex]
NEWS-G and SPCs

- The NEWS-G experiment uses spherical proportional counters (SPC) to search for low mass dark matter.

- SPCs are metallic spheres filled with gas, with a central anode producing a radial electric field.

- The last dark matter limits are from the SEDINE detector (60 cm diameter) at the Laboratoire Souterrain de Modane (LSM) in 2017.

- The latest detector, S140, is a 140 cm of diameter copper sphere which took data at the LSM in 2019, before being shipped to SNOLAB where it is currently taking data since 2022.

doi: 10.1016/j.astropartphys.2017.10.009
How an SPC works:

1. Atomic recoil causes ionization of the gas.
2. Primary electrons drift towards the central anode.
3. Townsend avalanche near the anode amplifies the signal.
4. Drifting secondary ions induce a current on the anode.

Sensor (achinos)

- NEWS-G now uses a multi-anode sensor that can achieve high gain while keeping a strong electric field at a high radius.
- The sensor is divided in two channels connecting the anodes of each hemisphere.
- A signal on one channel induces a negative signal on the other one (Shockley-Ramo effect).
- About 2/3 of the volume leads to the south anodes, due to the effect of the rod on the electric field.

Only pure south events are kept as candidate events.

[Diagram of sensor and anode distribution]
Shielding and data taking with S140

- The sphere is made of C10100 copper, with the inner 0.5 mm being electroformed ultra-pure copper.
- Lead, archeological lead and polyethylene (PE) make the shielding, although water was used at the LSM since the PE shield was unfinished.
- 10 days of physics data taken in 135 mbar of CH₄ at the LSM before the detector was shipped to SNOLAB.
- More time in SNOLAB to try more gas mixtures. Already 2 weeks with 1 bar of Ne + 2%CH₄. Now taking Ar + 5% CH₄ data.
Calibration

• A UV laser is directed at the inner copper surface of the sphere and releases electrons through the photoelectric effect. The UV light also goes to a photodetector so the laser events can be tagged.

• Some argon-37 is released inside the sphere, and the gas diffuses in the whole volume. This isotope is radioactive and has two peaks that enable energy calibration.

• Ionization yield (W-value) for CH₄ measured at Queen’s University.

• The nuclear quenching factor was measured at COMIMAC as well as obtained from literature W-values.

• New lower energy quenching factor measurements are planned at UdeM and RMTL, with the backing detector currently being built.

CAP 2024 – Jean-Marie Coquillat – May 27th
Peak counting and time separation

• The exponential decay of the preamplifier and the ion response are deconvolved from the raw signal.

• It is possible to count individual primary electrons.

• Surface events experience more diffusion than volume events, which causes the time separation between the first and last peak to be larger.
Alpha contamination

• There is $\sim 25 \text{ mHz}$ of alphas from either $^{222}\text{Rn}$ or $^{210}\text{Po}$ contamination in the copper surface.

• Alphas ionize a lot of gas and create a space charge that disturbs the electric field, and changes the electron drift time.

• Probably due to attachment, a high rate of low energy events keep happening for around 5s after each alpha.

• We remove most of the low-energy background due to alphas with a 5s cut after each one, keeping 85-90% of the total time.
Alphas in SNOLAB

- SNOLAB still has an alpha background with a similar rate. Etching of the inner surface has not removed the alphas.
- The increased rate of events after alphas is correlated with the impurity of the gas.
- The leading theory is that negative ions cause the delayed signals in the seconds after alpha events.
Pulse shape discrimination

• In the LSM, there were spurious pulses caused by electronic discharges in the data.

• Those can be discriminated from physical events with two different methods:
  ◦ Spurious pulses are either measurably spikier or wider than physical events.
  ◦ Spurious pulses do not cause a negative induced pulse on the opposite channel.

• Around 95% of the spurious pulses are removed with cuts using these discriminants, while still keeping 77% of the physical events.

• In SNOLAB, spurious pulses have been less numerous due to having more time to fix the electronics and remove them from the source.
Noise and data taking

Improvements from LSM:

• Trigger on three channels (North, South, PD) instead of only one at a time
• Reduced noise
• Better gas purity

• Gas purifier from University of Birmingham
  ◦ Oxygen removal from copper balls and molecular sieve

• Silver zeolite radon trap from University of Alberta
  ◦ New installation this week after adjustments

• Time to try multiple gas mixtures:
  Ne+2%CH₄, Ar+CH₄, Ne+7%CH₄, CH₄, He+CH₄ etc.
LSM preliminary limits

• 30% of the full data was set aside as a test data before the rest is unblinded.
• Profile likelihood fits of the test data were made for 2-3-4 peak data
• Fits with contributions from surface background, coincidences and WIMP signal.
• No significant WIMP signal was detected. WIMP exclusions limits with ~0.12 kg·days of data
• Strongest constraints for the proton spin-dependent interaction in the 0.2 - 1.5 GeV range.
• Final blind data results to come soon: paper currently in internal review.

SNOLAB data analysis

Here are some preliminary results from the neon data taken in Winter 2023:

- Laser calibration fits show the contributions from all numbers of primary electrons.
- MCMC fits of $^{37}$Ar data show the different gains of each southern anode of the sensor.
- Physics test data hints at a lesser contribution from the single-electron background compared to the LSM.
Conclusion

- NEWS-G and SPCs well suited for low mass dark matter search.

- LSM data able to set new SD-p WIMP constraints with CH$_4$.

- Currently taking improved physics data at SNOLAB.

- Expecting even better results from the SNOLAB data.
Extra slides
Future projects

- **ECuME (& miniECuME):**
  - Fully underground electroformed 140 cm of diameter copper sphere in SNOLAB. (tests ongoing at PNNL)

- **DarkSPHERE:**
  - Fully electroformed 3m of diameter sphere in a water shield. (under consideration)

- **NEWS-G3:**
  - Shield at Queen’s University intended for CEvNS detection at nuclear reactors. (shield completed, started testing)
Making the sphere, electroforming, etching
Birmingham Purifier
- oxygen removal
- copper balls + molecular sieve
- installed at SNOLAB
- few 10mBq radon

Radon trap
- silver zeolite
- tested at UoA
- in 10cm long, 10mm diameter SS pipe
- installed at SNOLAB
  - too much resistance for circulation
  - wider and 5x larger trap under construction
    (in CF40 pipe (34mm diameter))
Quenching factor

Quenching Factor of H in CH₄

Double deconvolution

The ballistic deficit is the signal amplitude that gets underestimated due to the exponential decay of the preamplifier. The full amplitude (energy) is retrieved by doing a double deconvolution of the raw signal, and then integrating the pulses.
Alpha background

There is $^{210}$Po contamination in the copper surface, which causes alphas that ionize a lot of gas. All the ions create a space charge that disturbs the electric field, and changes the electron drift time. For some still unknown reason, a high rate of low energy events keep happening for around 5s after each alpha.

The saturated alpha signals can be broken up and difficult to detect, but using the drift time, rate of events and decreasing baselines, we can identify alphas and remove most of the low-energy background due to them with a 5s cut after each alpha, keeping 85-90% of the total time.
Spikiness

1\textsuperscript{st} comparison method
Spikiness

\[ \text{Spk} = \frac{\text{Max signal derivative}}{\text{Peak height}} \]

Probable electron event

Probable spike event

CAP 2024  –  Jean-Marie Coquillat  –  May 27\textsuperscript{th}
North/South integral ratio

2\textsuperscript{nd} comparison method

N/S ratio

\[
\text{Probable electron event} \quad \text{Probable spike event}
\]

\[
\frac{\text{North DD2 integral}}{\text{South DD2 integral}} = \frac{\sum_{\text{North}}}{\sum_{\text{South}}}
\]

Various N/S

- Spikes
- Ar-37 270 eV
- Laser 120A
- Ar-37 2.8 keV

CAP 2024  –  Jean-Marie Coquillat  –  May 27\textsuperscript{th}
Linear Fisher discriminant

Optimal comparison:
Combining both methods

Separation $J(\omega) = \frac{(\mu_1-\mu_2)^2}{N_1(\sigma_1)^2 + N_2(\sigma_2)^2}$

New axis $\tau_i = \omega^t x_i^t$

$\omega = [-0.678619815, -76.8674863]$  
Spk  NS

CAP 2024  –  Jean-Marie Coquillat  –  May 27th
Fits to the physics data

The separation between electron and spike events is weaker at lower energies.

Wide pulses are another dominant background of unknown origin in the data.

A cut on N/S removes fat pulses (dominant in 2-peak data) and a Fisher discrim. cut removes spikes.
