Today's topics

Brief summary of my works in this direction

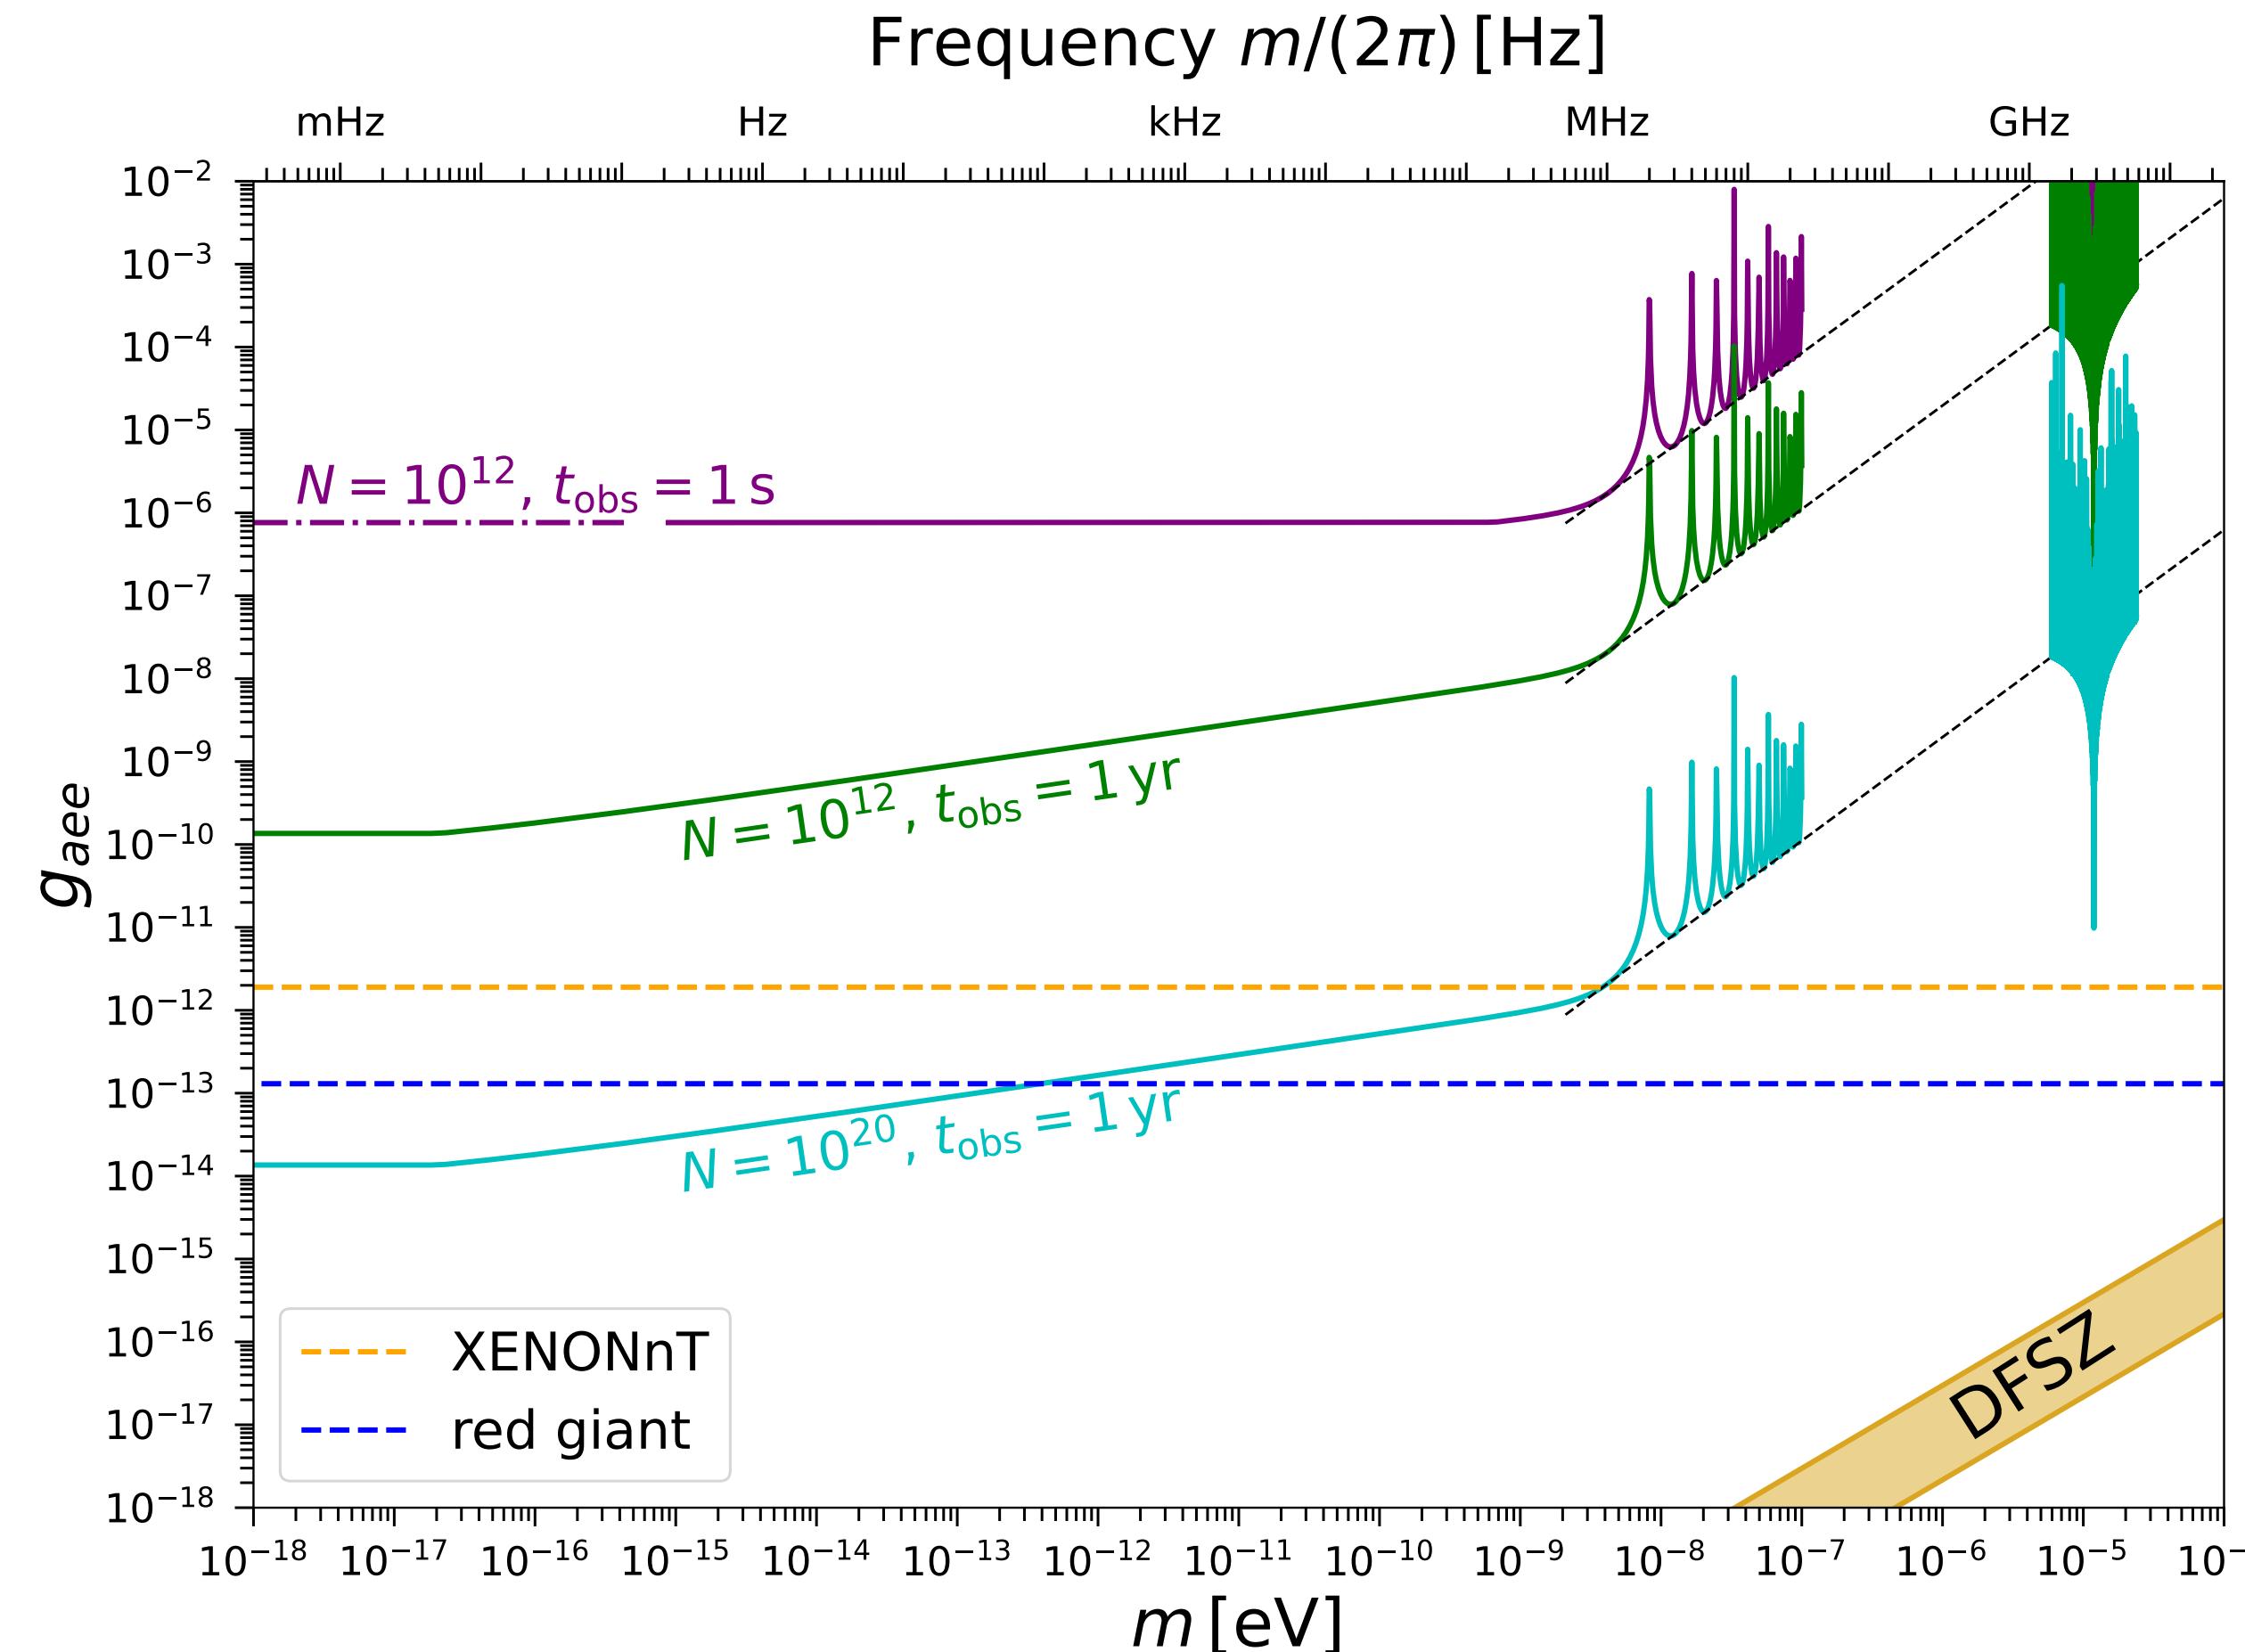

# Narrow-band search: magnon

- Light axion DM converts into a collective excitation of spin = magnon

# Broad-band search with NV centers

- ▶ NV center has “wide dynamic range”

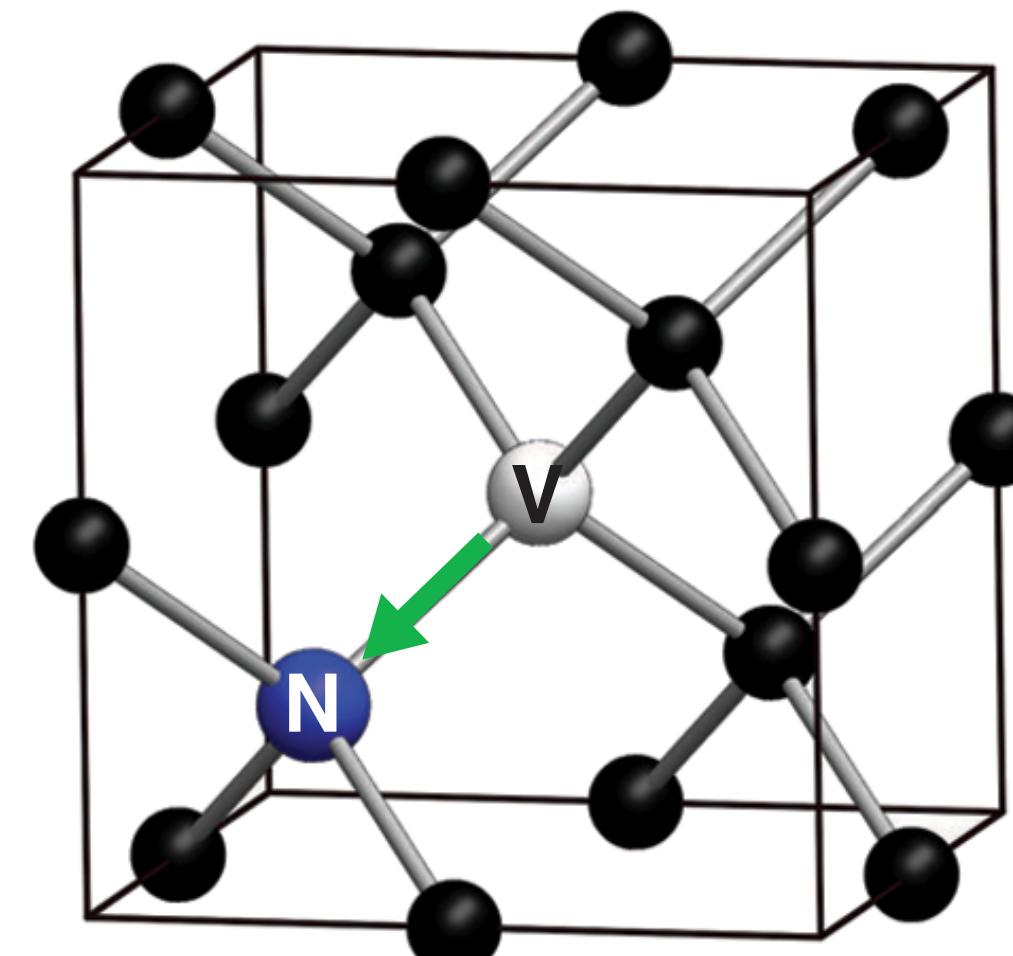

# Table of contents

- ▶ Introduction to NV center
  - What is it? How does it work as a quantum sensor?
- ▶ NV center magnetometry for DM detection
  - DC magnetometry + application to axion DM
  - Why wide dynamic range?
  - AC magnetometry + application to axion DM
- ▶ Experimental status
- ▶ Discussion & conclusion

# Introduction to NV center

# NV center in diamond

(a)

L. M. Pham '13

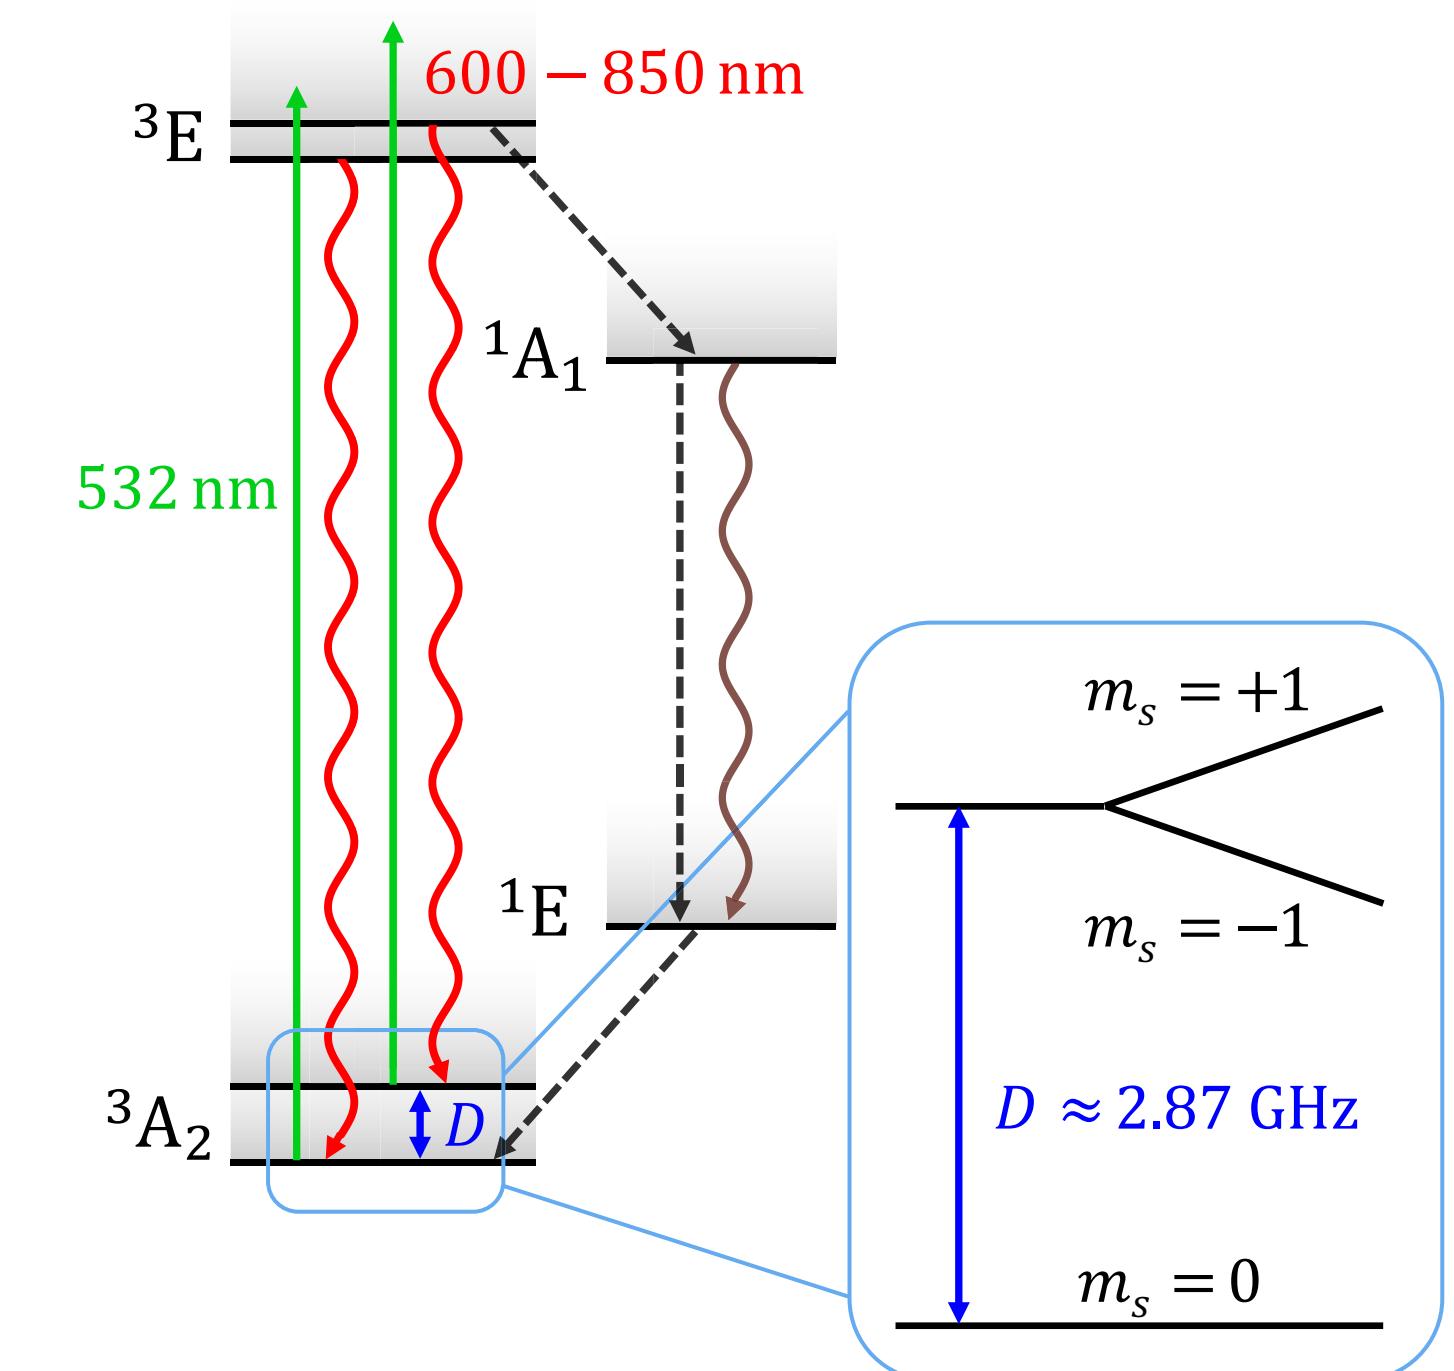

“pink diamond”

- ▶ The bound state of substitutional nitrogen (N) and vacancy (V) in diamond
- ▶ The charged state  $\text{NV}^-$  has two extra  $e^-$ s localized at V
- ▶ The ground state:  $e^-$  orbital singlet,  $e^-$  spin triplet  $S = 1$  system

# Fluorescence

- ▶ Can distinguish spin states  $|m_s = 0\rangle$  and  $|m_s = \pm\rangle$  by fluorescence measurement
- ▶ Governed by following processes + selection rules
  - ${}^3A_2 + 532\text{ nm photon} \rightarrow {}^3E$
  - ${}^3E \rightarrow {}^3A_2 + 600 - 850\text{ nm photon}$
  - ${}^3E_{S \neq 0} \rightarrow ({}^1A_1 \rightarrow {}^1E) \rightarrow |m_s = \pm\rangle + \text{infrared photon}$
- ▶ The spin state  $|\psi\rangle = \cos \frac{\theta}{2} |0\rangle + \sin \frac{\theta}{2} |\pm\rangle$  is read from strength of the red (pink) fluorescence light

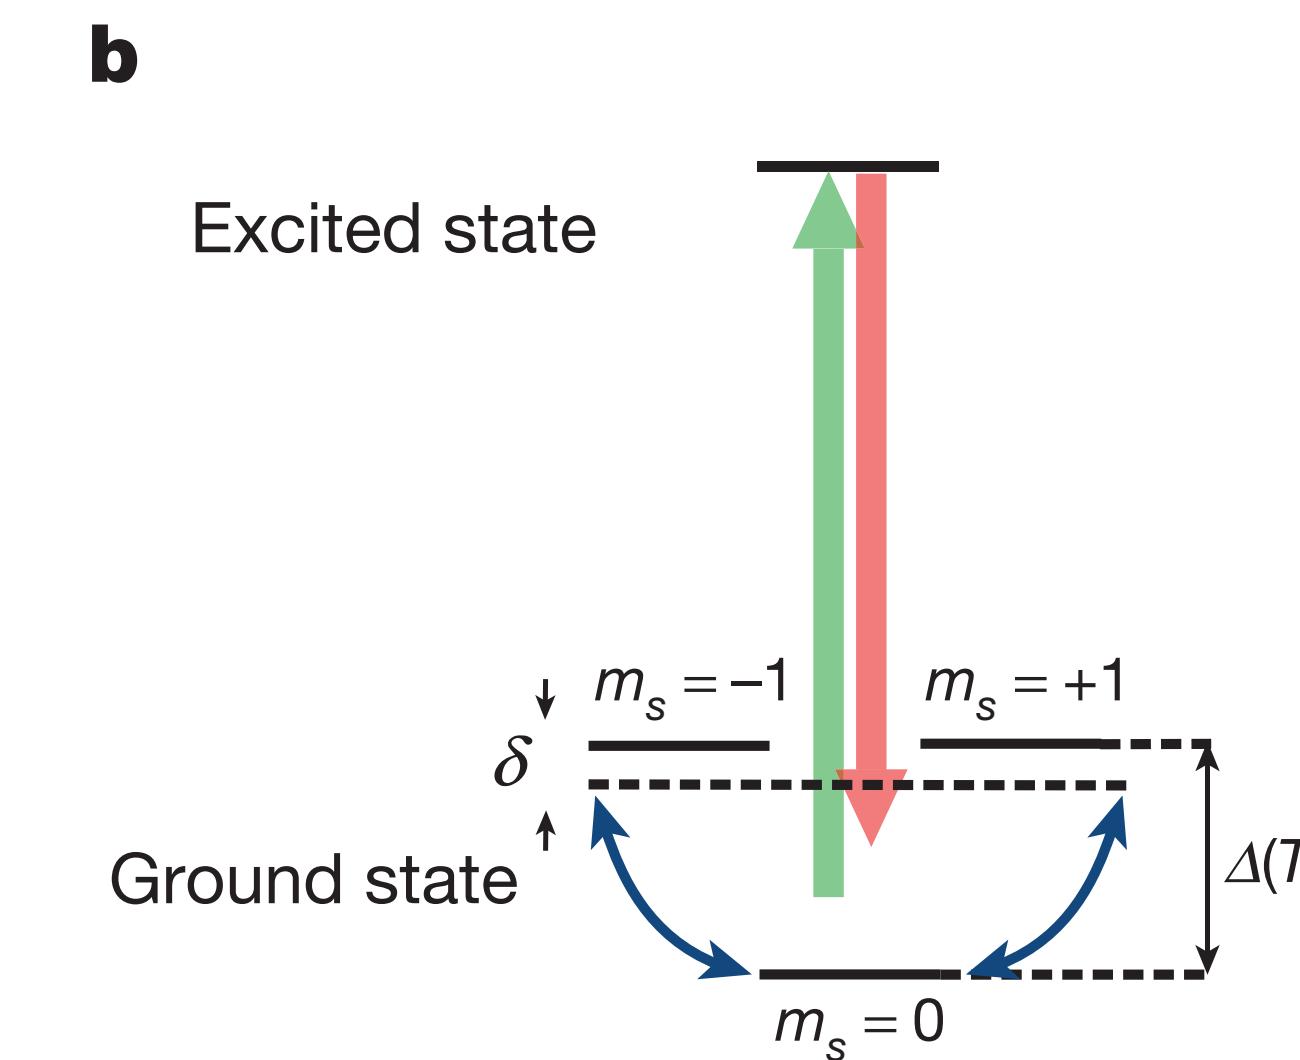

J. F. Barry+ '20

# NV center as a quantum sensor

- NV center works as a multimodal quantum sensor M. W. Doherty+ [1302.3288]

1. Temperature G. Kucsko+ '13
2. Electric field F. Dolde+ '11
3. Strain M. Barson+ '17
4. Magnetic field (explain later)
  - No cryogenics
  - No vacuum system
  - No tesla-scale applied bias fields are required
  - Wide dynamic range

- Two options
  - Single NV center (high spacial resolution)
  - Ensemble of NV centers (high sensitivity) with  $\sim 1 - 20$  ppm concentration

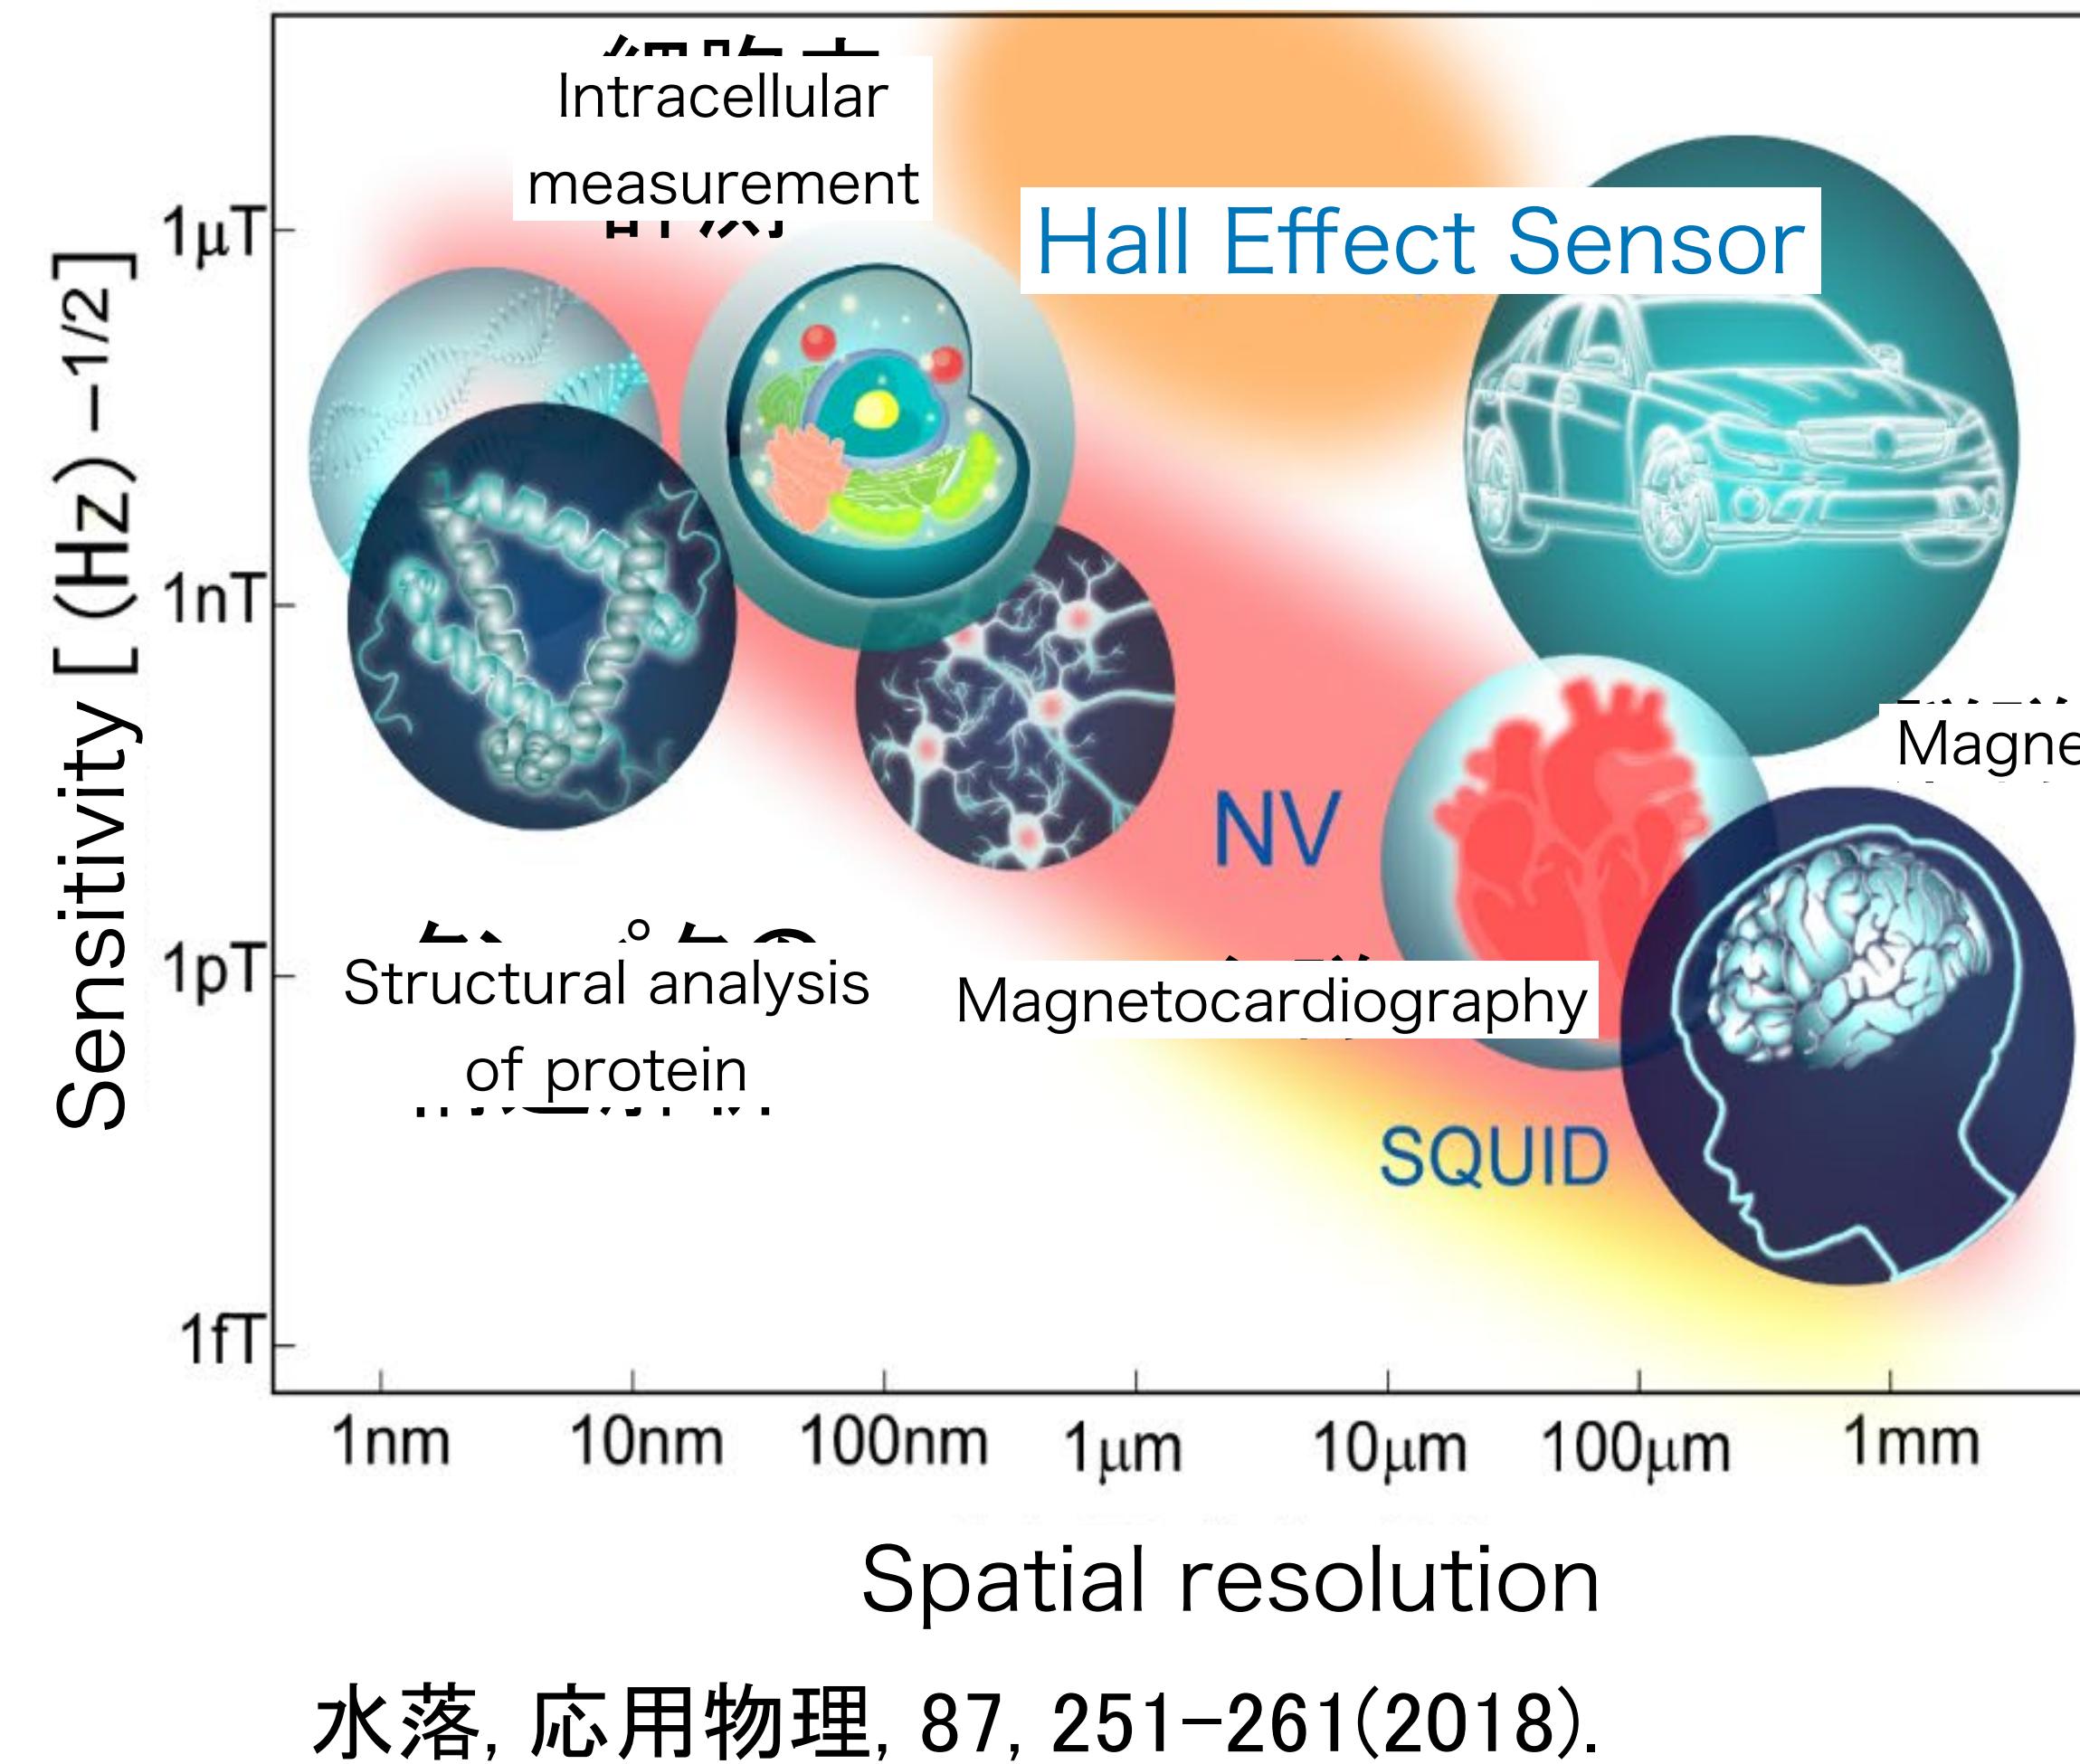

# Applications of NV center magnetometry

- ▶ Single NV center

- $B_{ac} \sim 9.1 \text{ nT Hz}^{-1/2}$

- $B_{dc} \sim 10 \text{ nT Hz}^{-1/2}$

- D. Herbschleb+ '19

- ▶ Ensemble

- $B_{ac} \sim 210 \text{ fT Hz}^{-1/2}$

- $B_{dc} \sim 460 \text{ fT Hz}^{-1/2}$

- J. F. Barry+ '23

# DC magnetometry

# Rabi cycle

- Energy gap  $\Delta E \sim 2\pi \times 2.87 \text{ GHz}$
- Under the transverse magnetic field

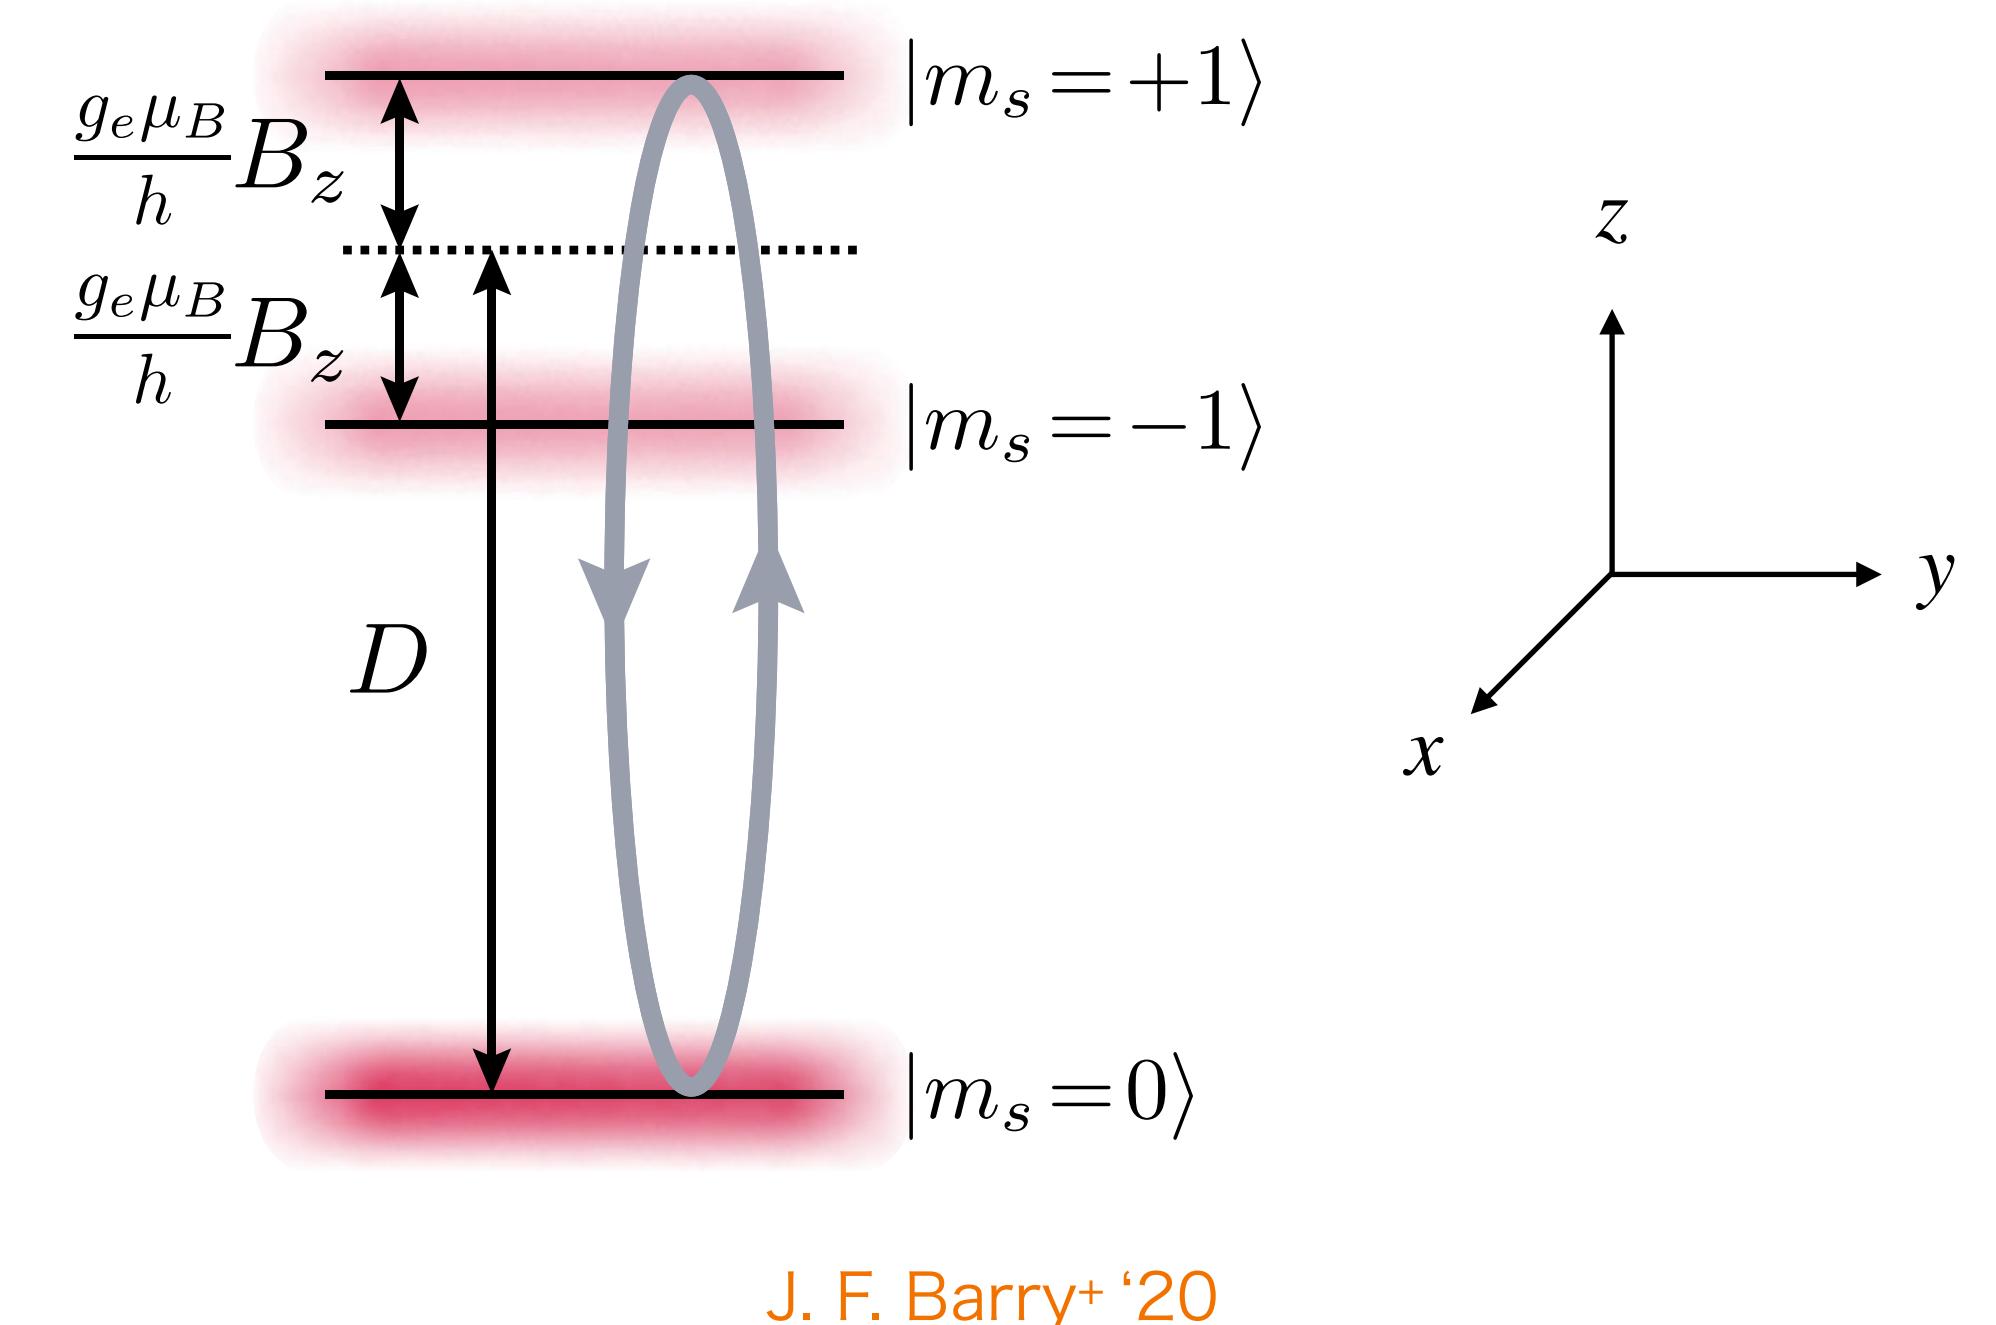

$$\mathbf{B}_1 = B_{1y} \hat{\mathbf{y}} \sin(2\pi ft) \text{ with frequency}$$

$$f = D + \frac{1}{2\pi} \gamma_e B_z$$

- Time evolution is described by the Rabi cycle

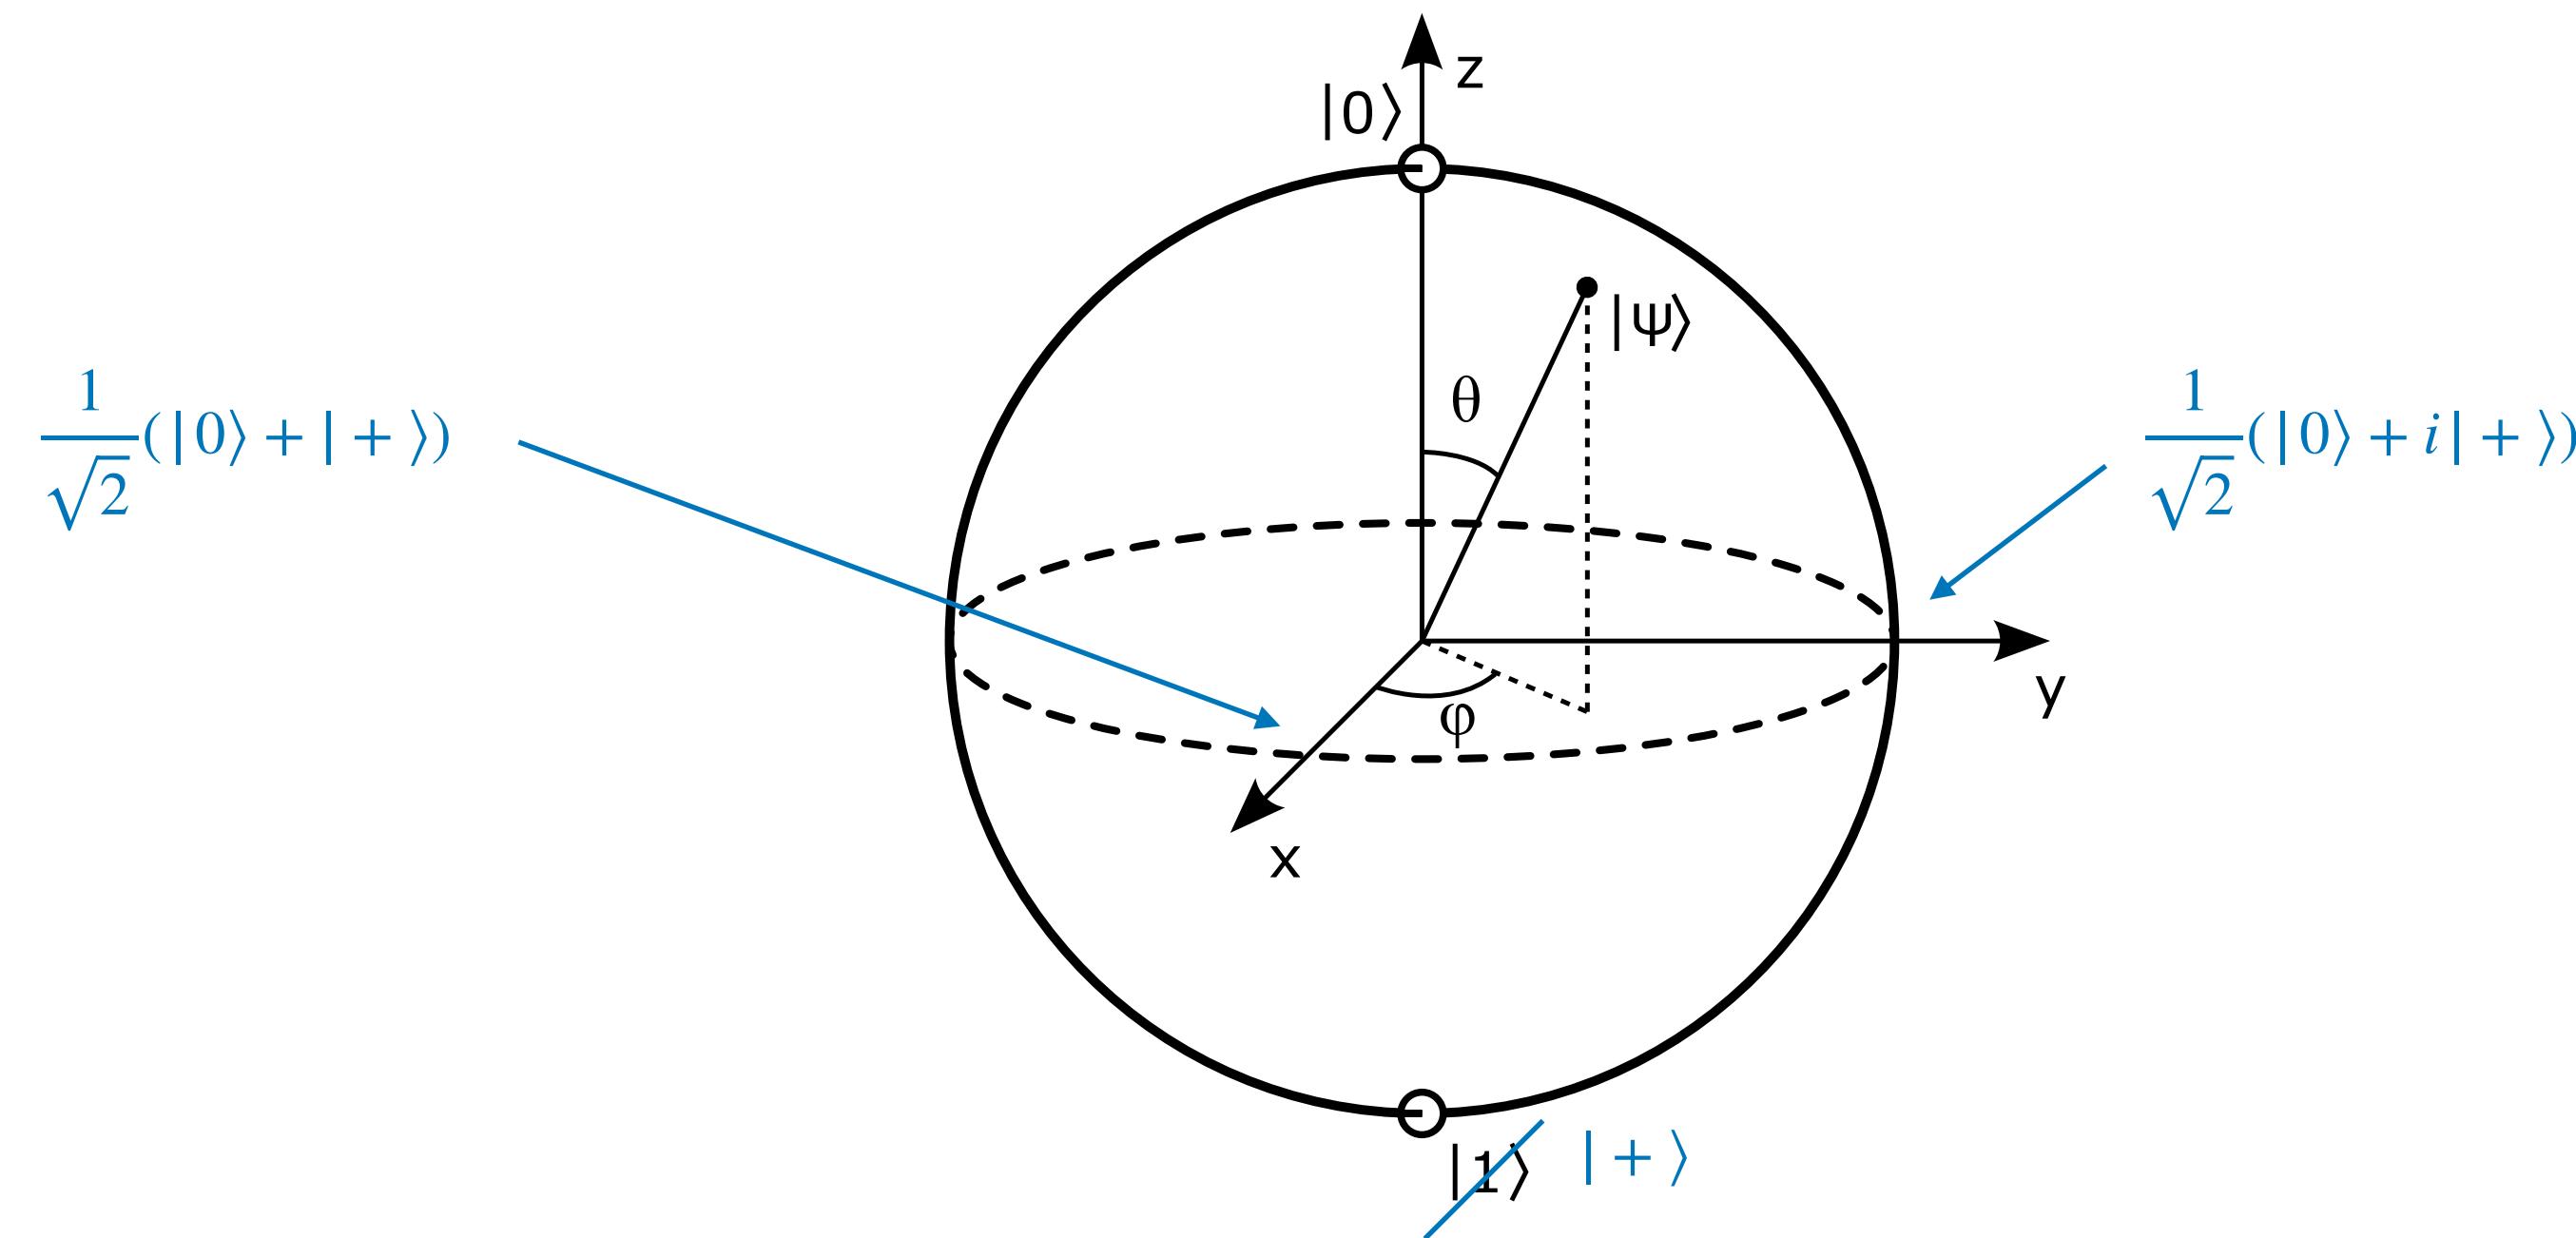

$$|\psi(t)\rangle = \cos\left(\frac{1}{\sqrt{2}}\gamma_e B_{1y} t\right)|0\rangle + \sin\left(\frac{1}{\sqrt{2}}\gamma_e B_{1y} t\right)|+\rangle$$

- $|-\rangle$  is irrelevant
- qubit system of  $|0\rangle$  and  $|+\rangle$

J. F. Barry<sup>+</sup> '20

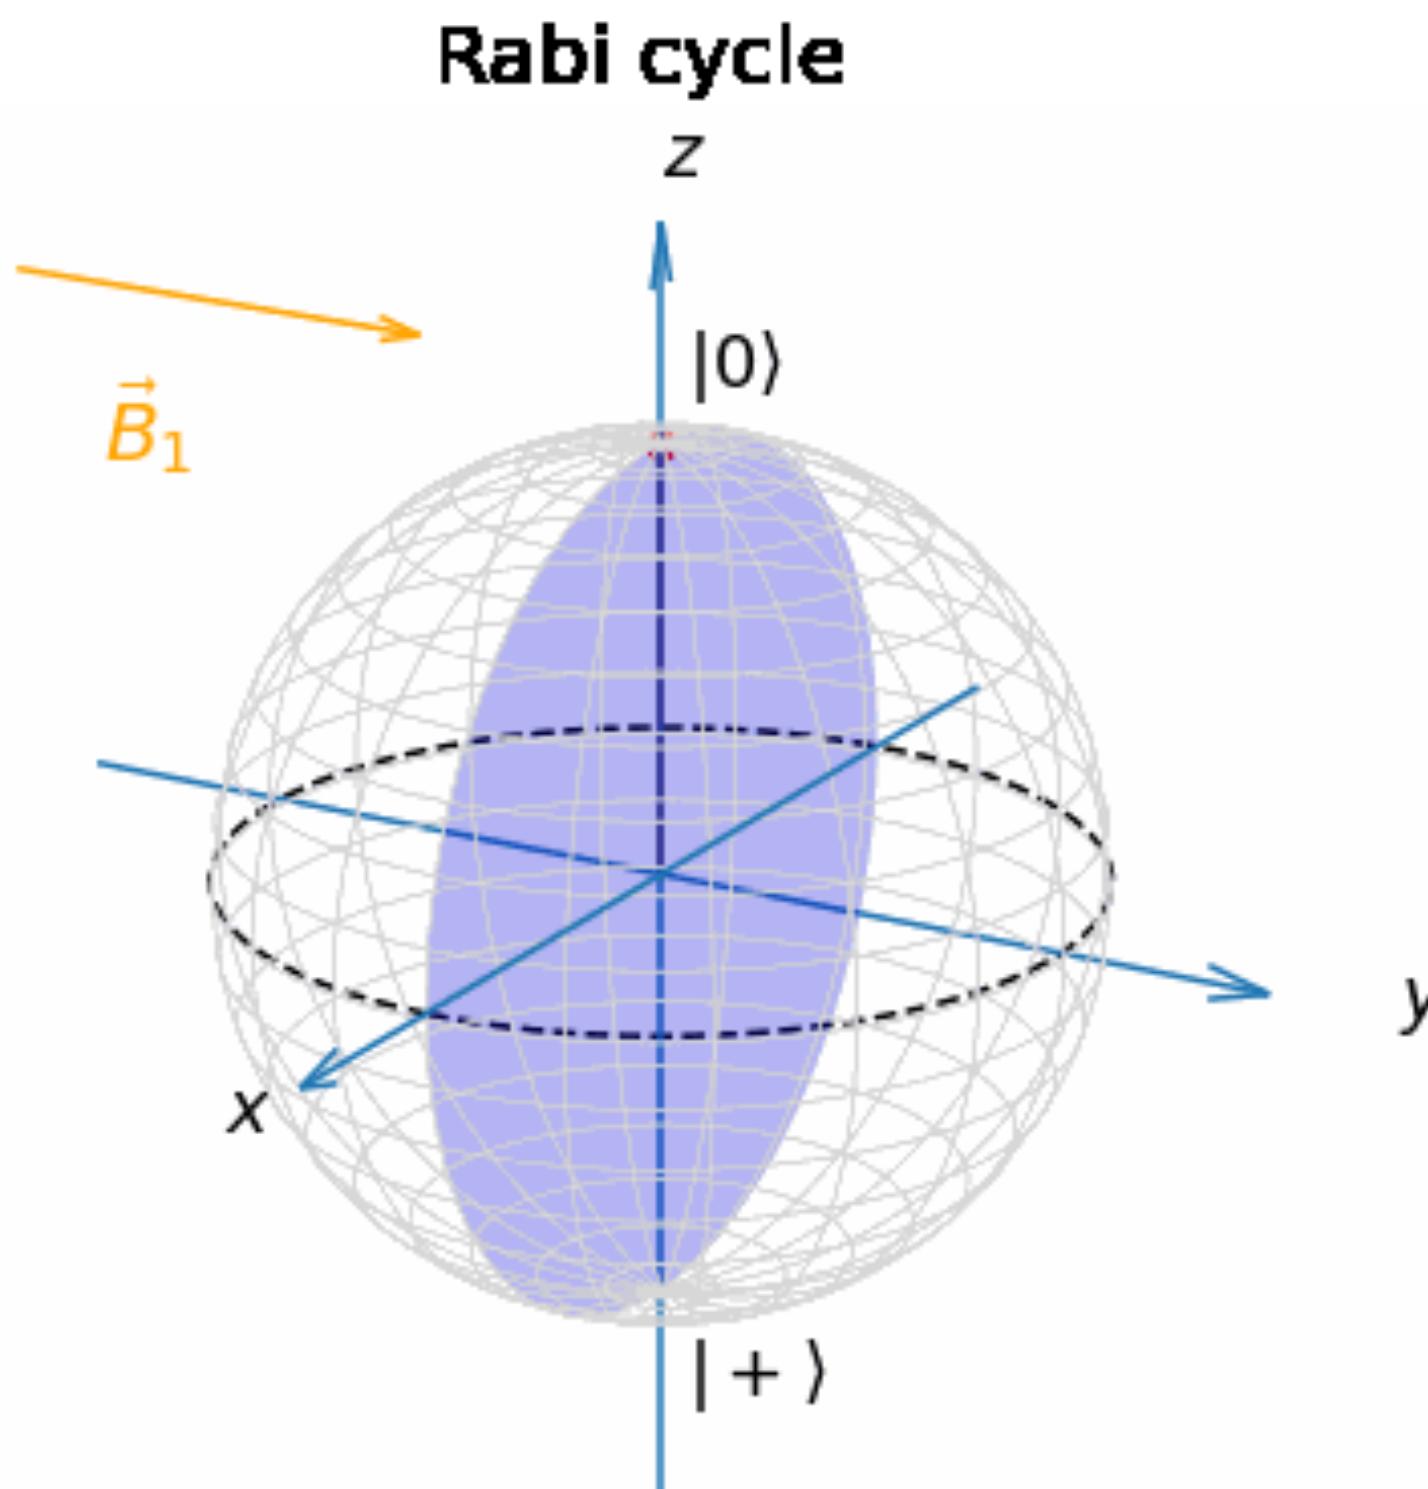

# Bloch sphere

- Each point on sphere  $S^2$  corresponds to a state  $|\psi\rangle$  in the qubit system

Polar coordinate  $(\theta, \phi) \rightarrow |\psi\rangle = \cos \frac{\theta}{2} |0\rangle + \sin \frac{\theta}{2} e^{i\phi} |+\rangle$

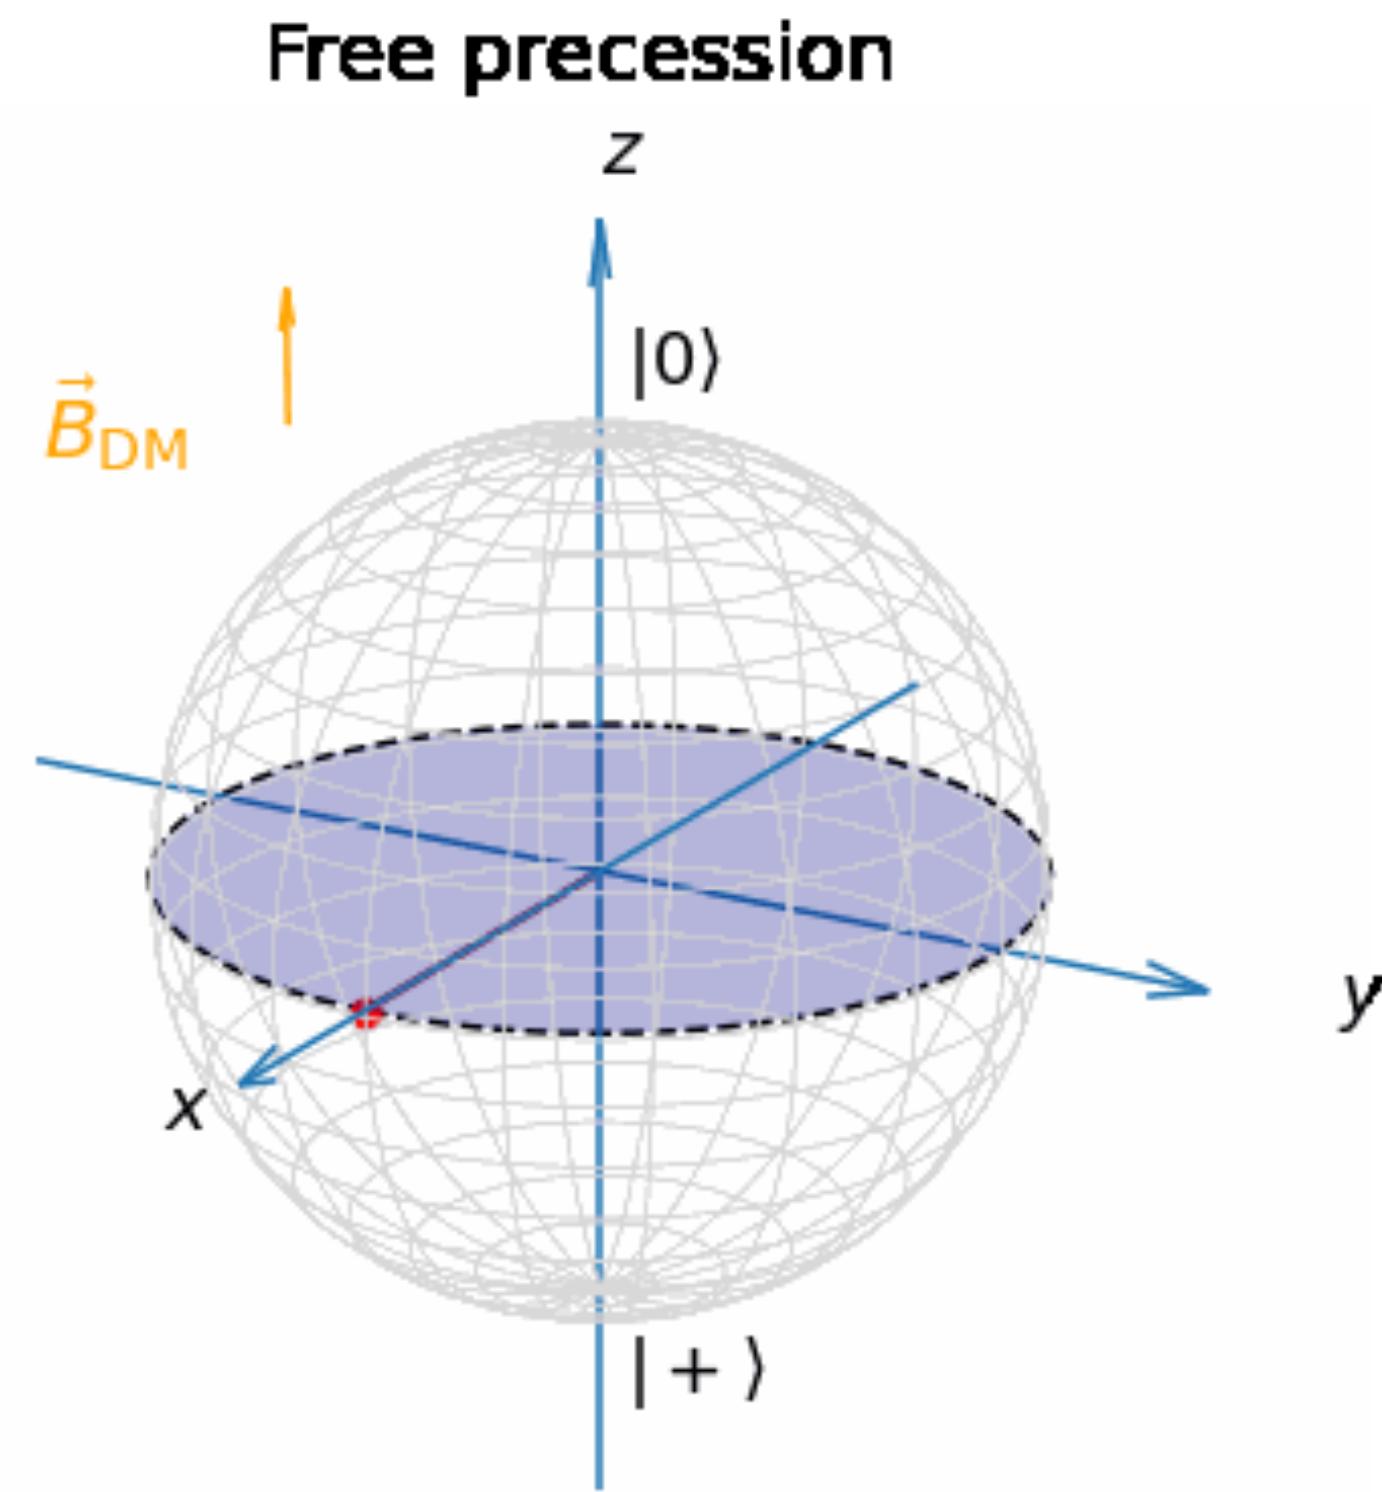

# Rabi cycle on Bloch sphere

- Rotation around  $\vec{B}_1 \propto \hat{y}$

$$|\psi(t)\rangle = \cos \frac{\theta(t)}{2} |0\rangle + \sin \frac{\theta(t)}{2} |+\rangle \text{ with } \theta(t) = \sqrt{2}\gamma_e B_{1y} t$$

# Free precession

- Magnetic field  $\vec{B} \propto \hat{z}$  causes free precession = rotation around  $\hat{z}$

$$|\psi(\tau)\rangle = \frac{1}{\sqrt{2}} (|0\rangle + e^{i\varphi(\tau)}|+\rangle) \text{ with } \varphi(\tau) = \gamma_e \int_0^\tau dt B_{\text{DM}}^z(t) \simeq \gamma_e B_{\text{DM}}^z \tau \text{ (for DC-like signal)}$$

# Ramsey sequence

## Ramsey sequence for DC magnetometry

1.  $(\pi/2)_y$  pulse

- Rabi cycle with  $\theta = \sqrt{2}\gamma_e B_{1y} t = \pi/2$

2. Free precession under  $\mathbf{B}_{\text{DM}}$  for duration  $\tau$

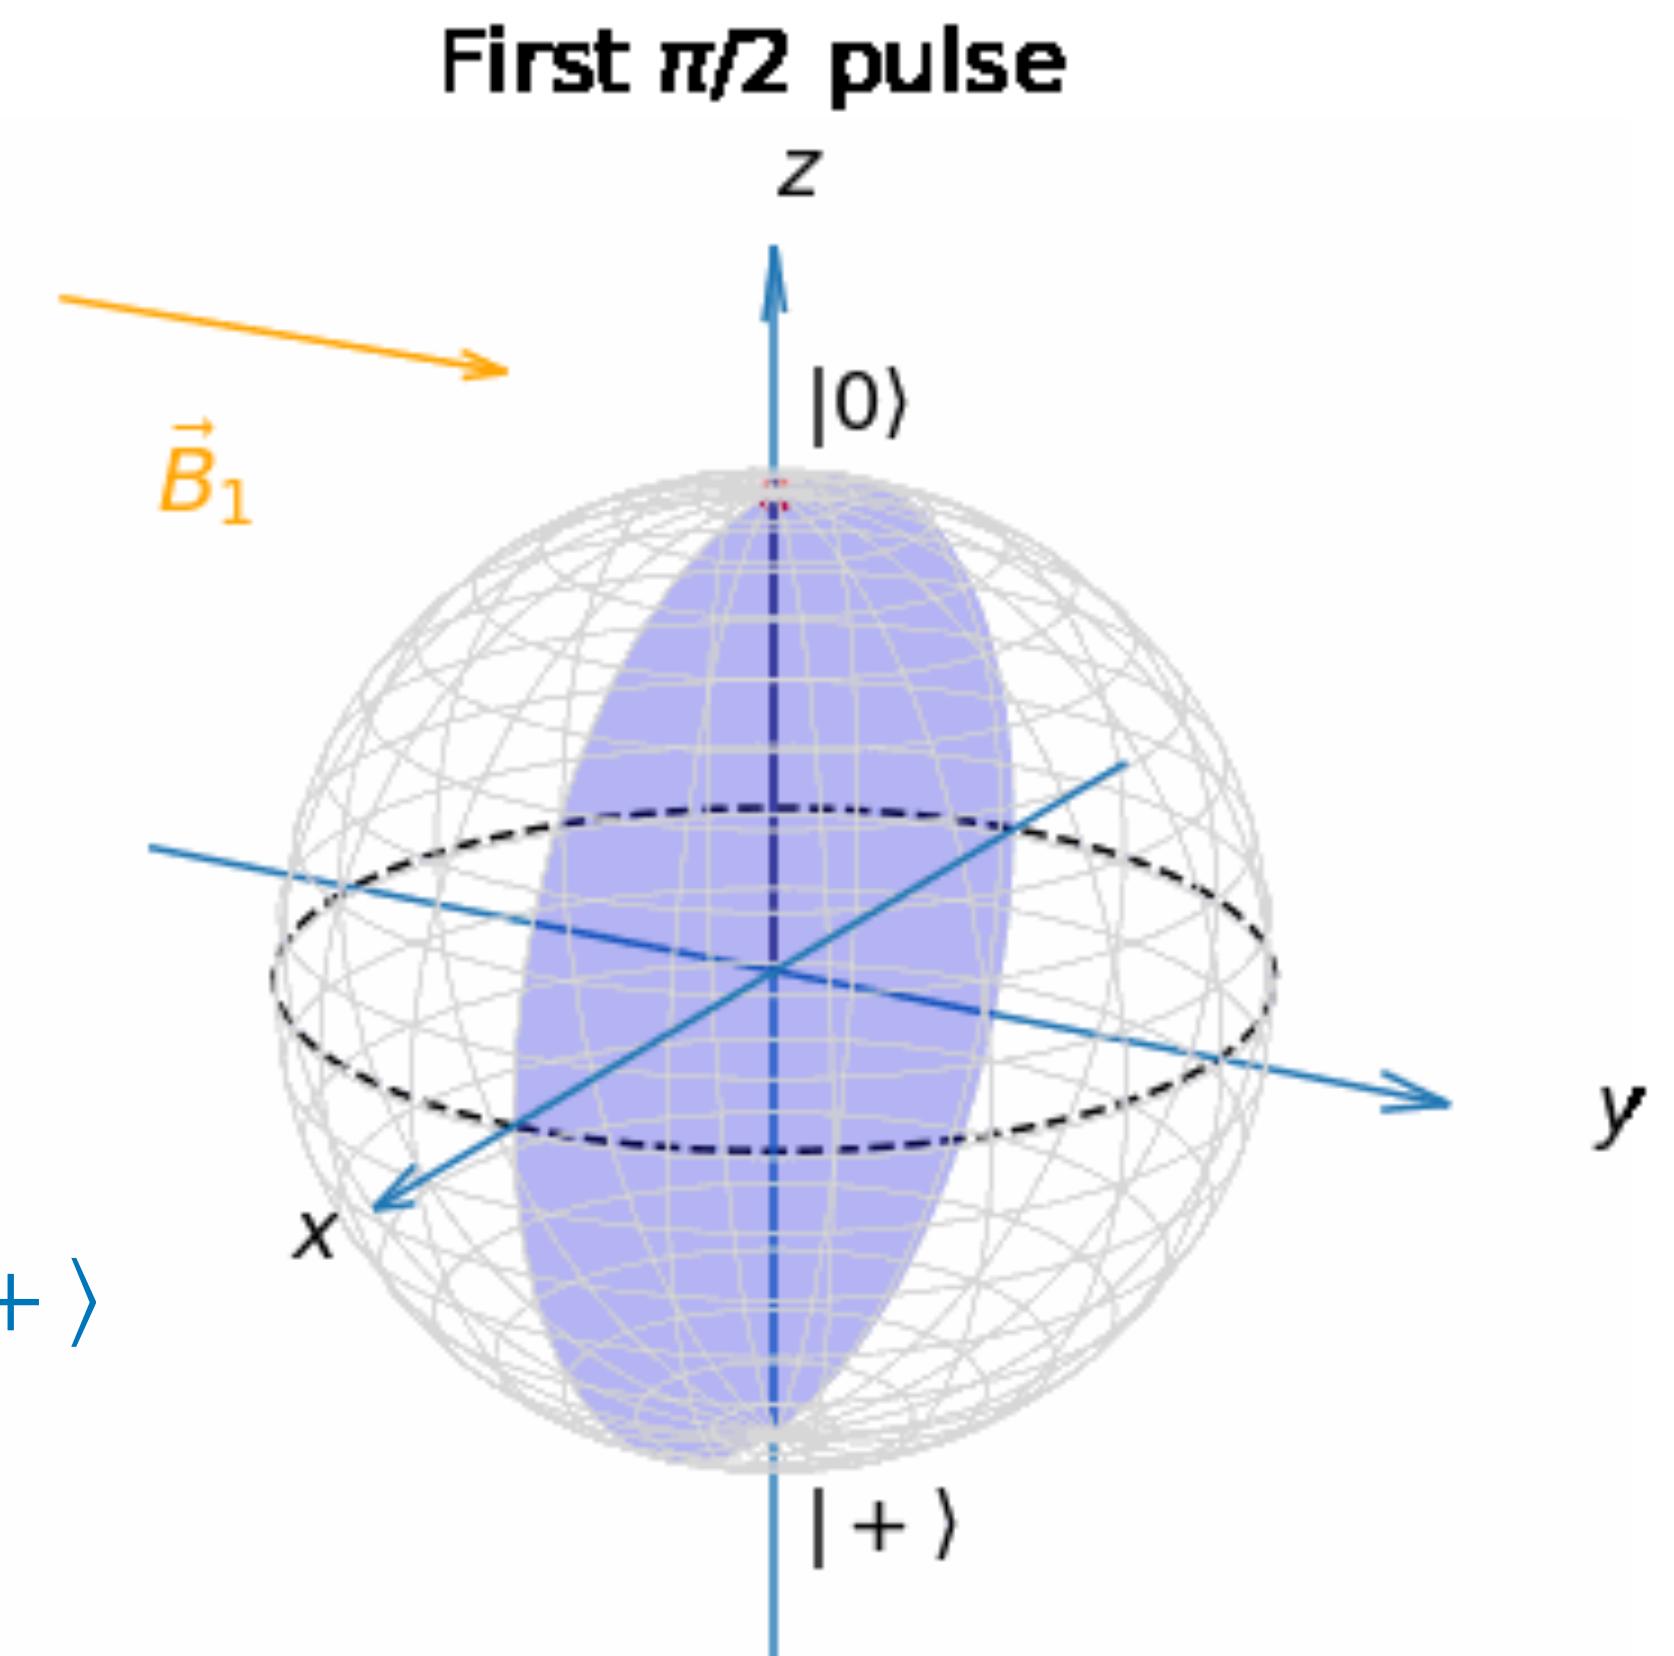

3.  $(\pi/2)_x$  pulse

4. Fluorescence measurement

- DM signal is population difference between  $|0\rangle$  and  $|+\rangle$

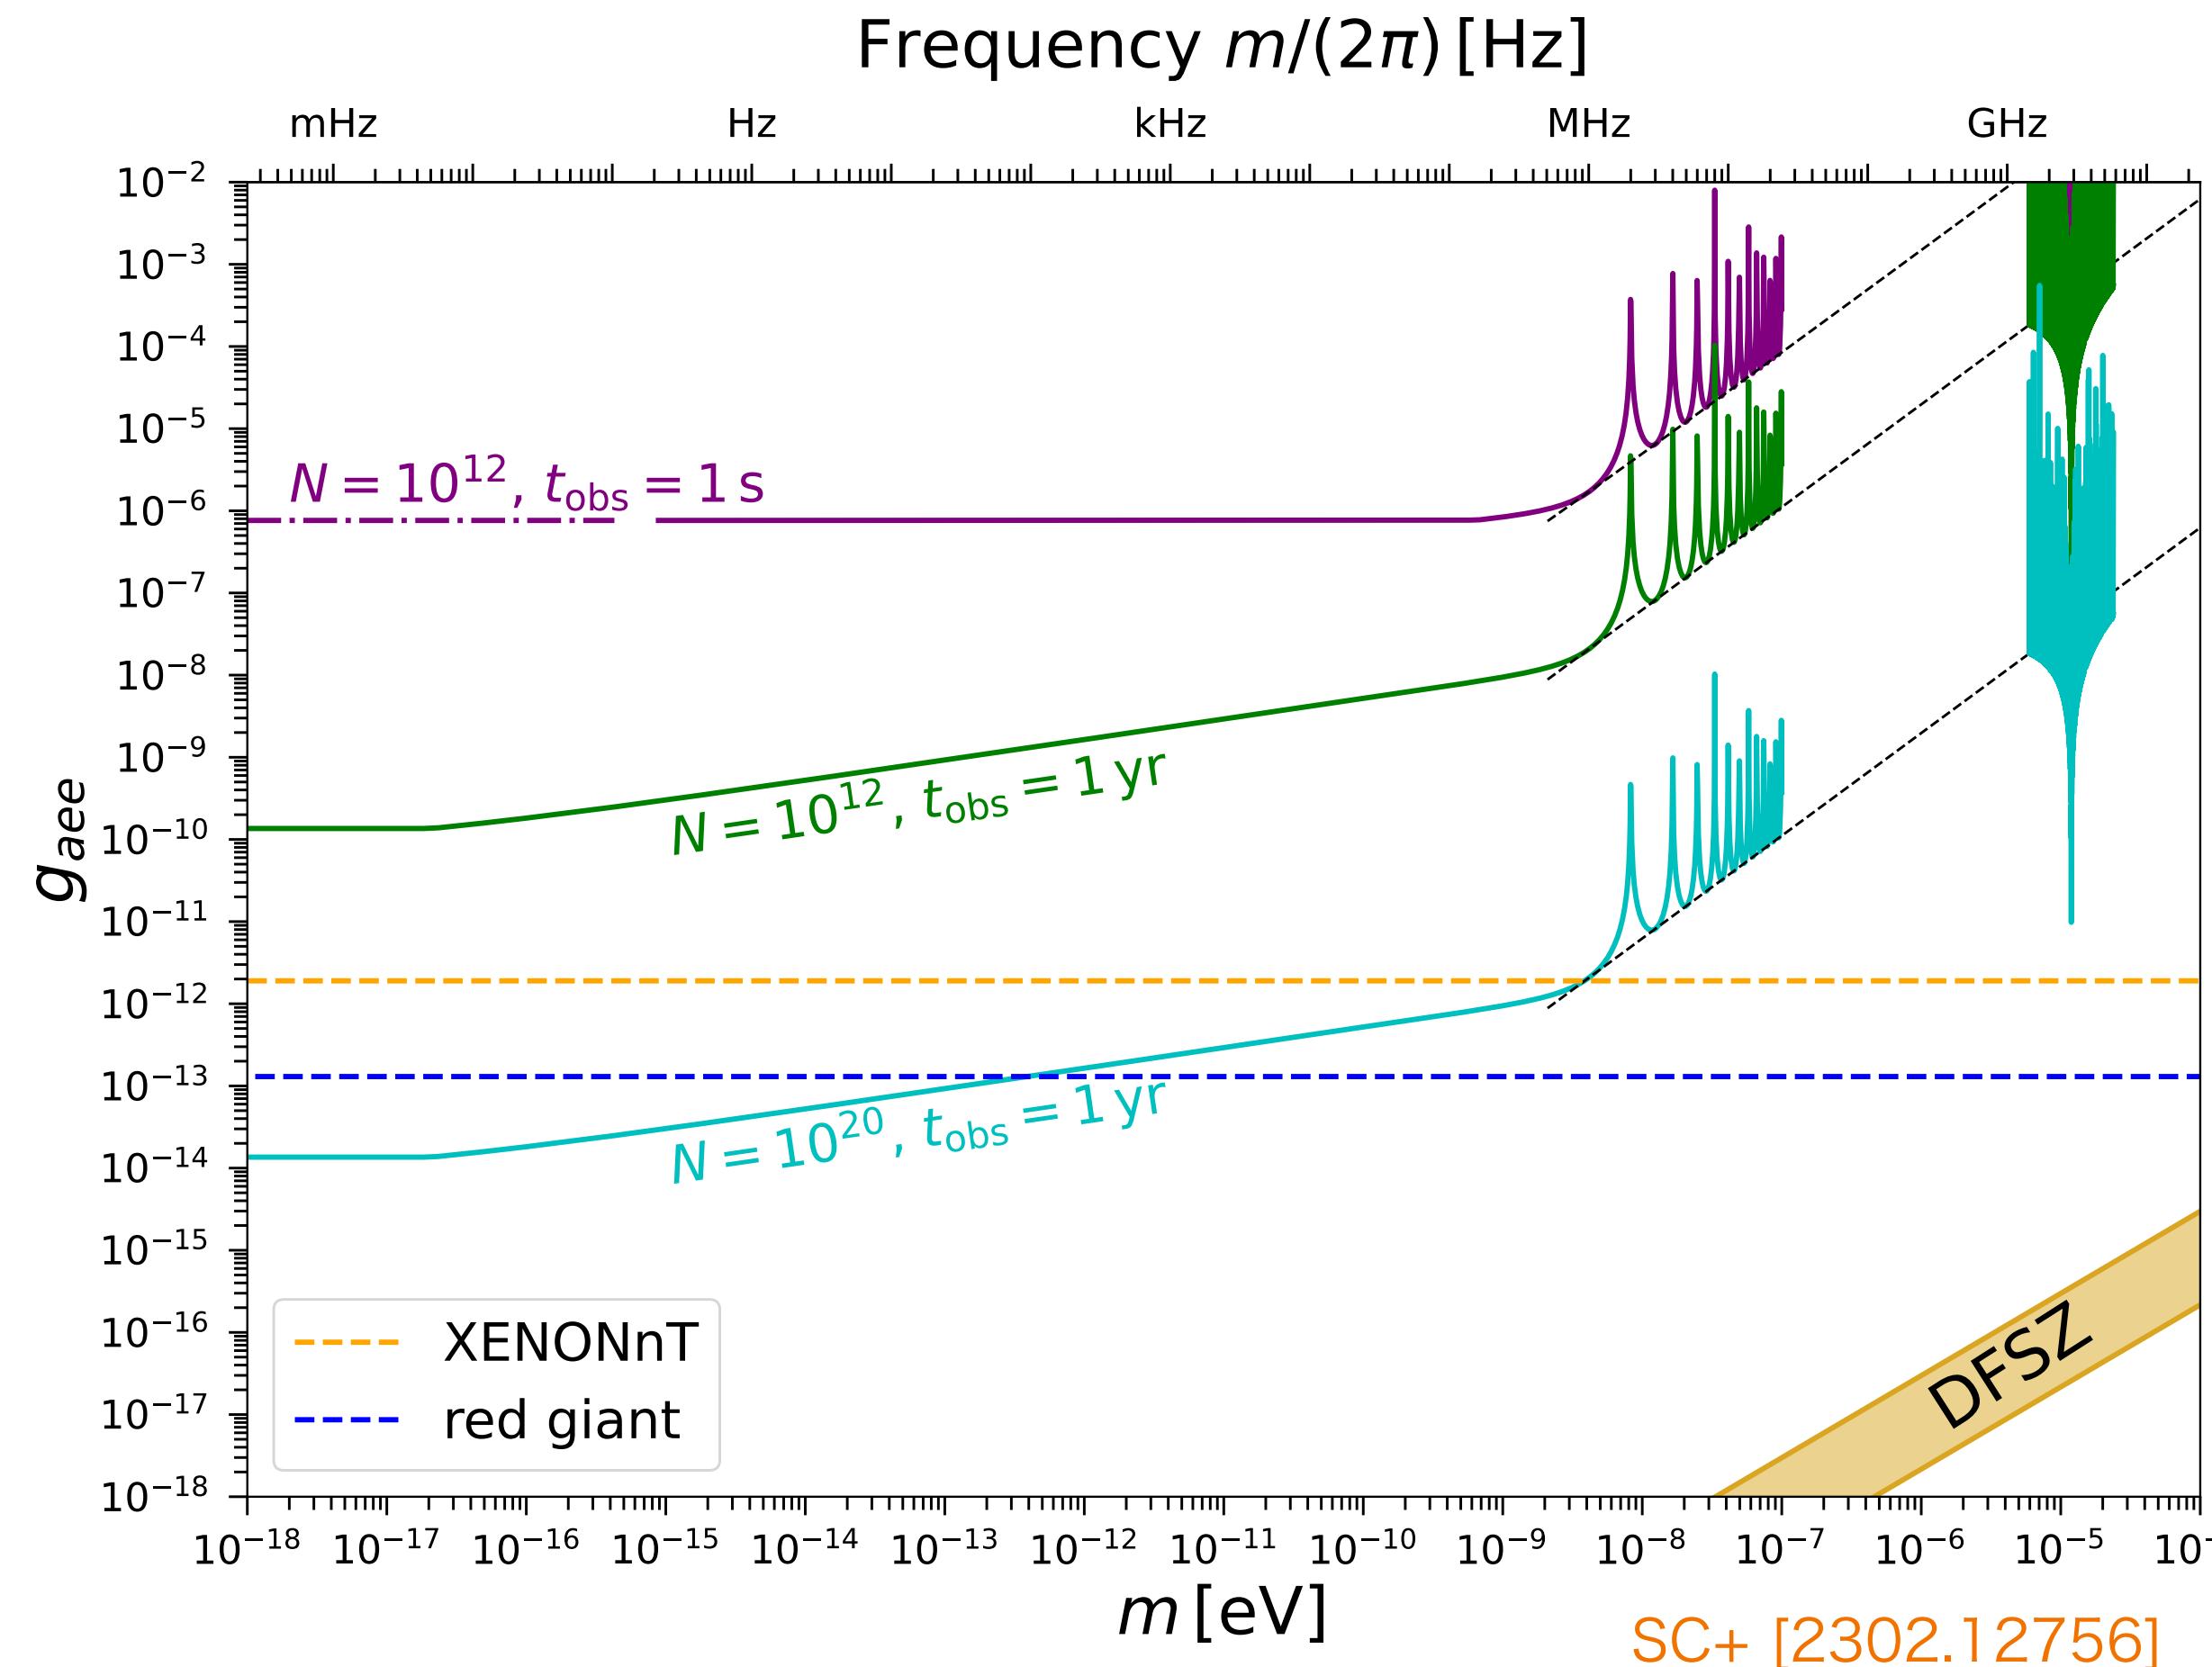

$$S \equiv \frac{1}{2} \langle \psi_{\text{fin.}} | \sigma_z | \psi_{\text{fin.}} \rangle \propto \varphi(\tau) \simeq \gamma_e B_{\text{DM}}^z \tau$$

- Best choice is  $\tau \sim T_2^* \sim 1 \mu\text{s}$  : spin relaxation (dephasing) time

# Sensitivity on axion DM

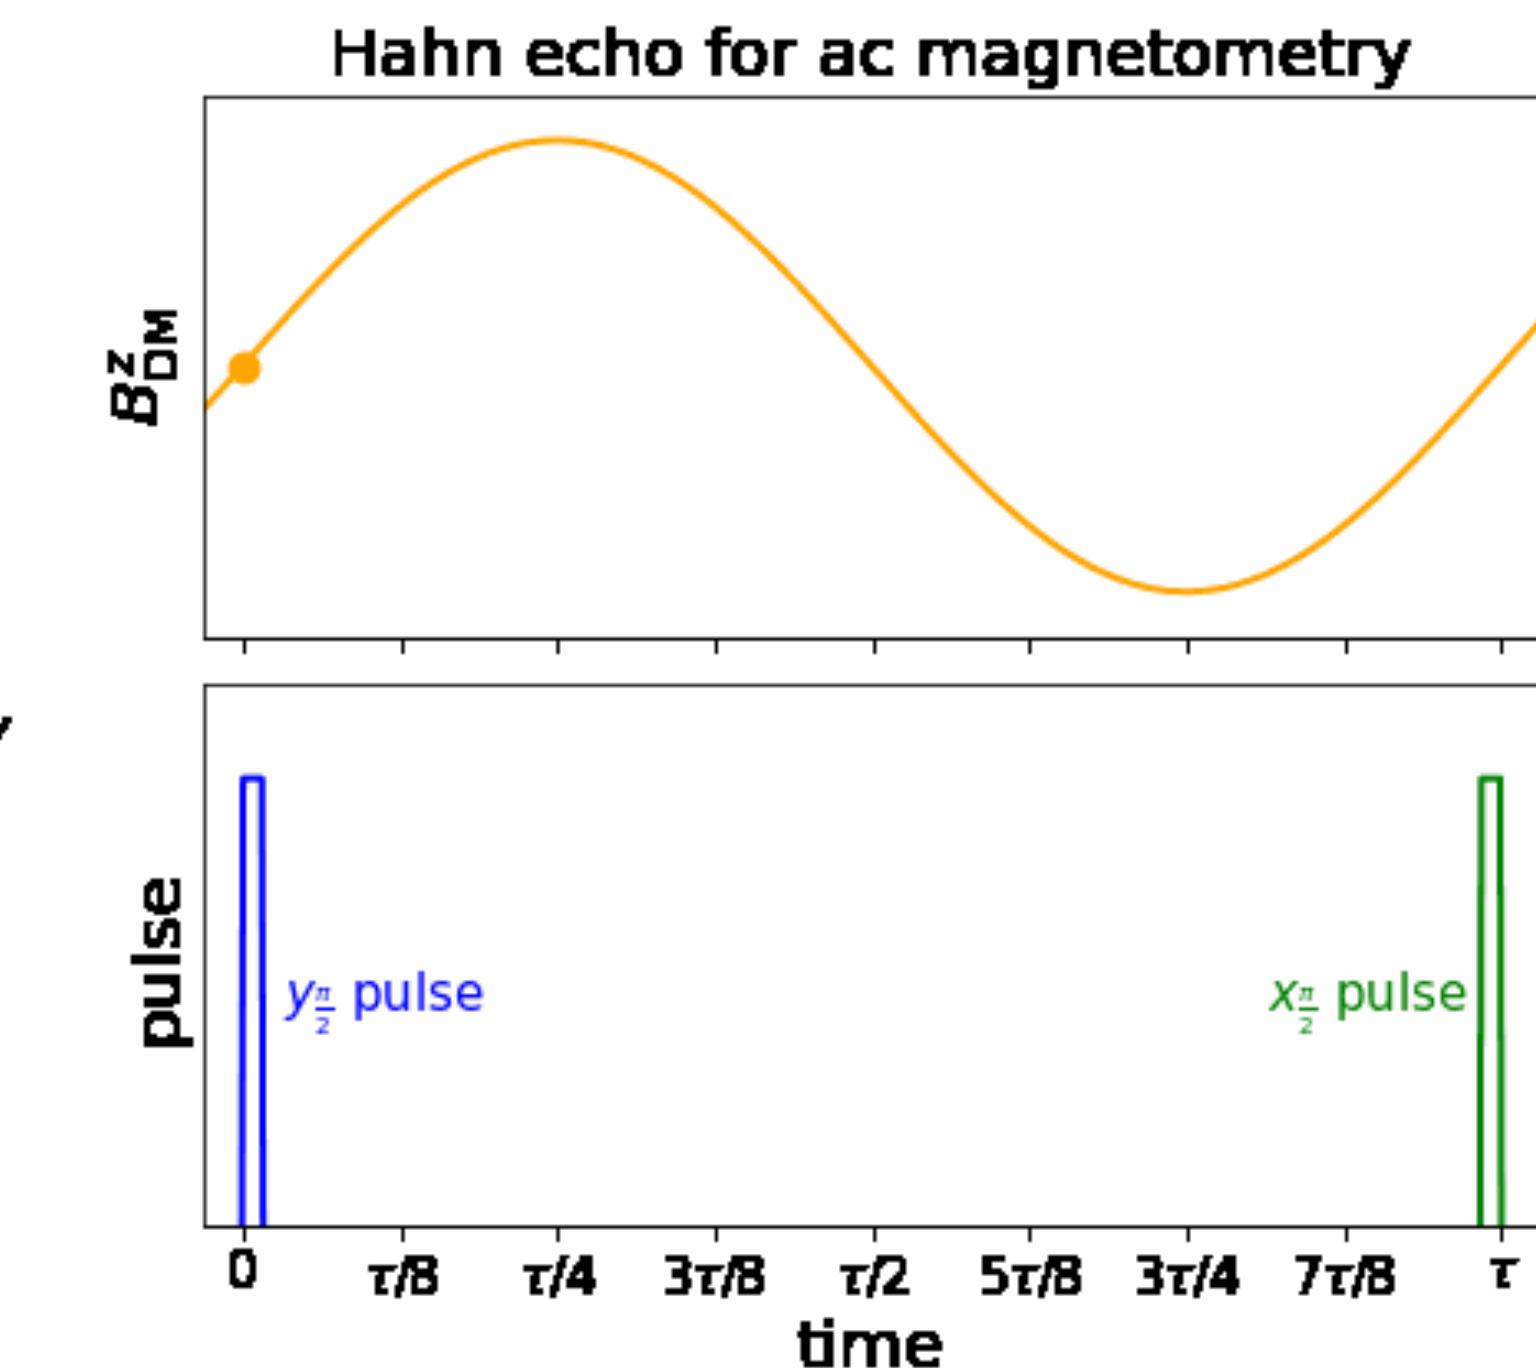

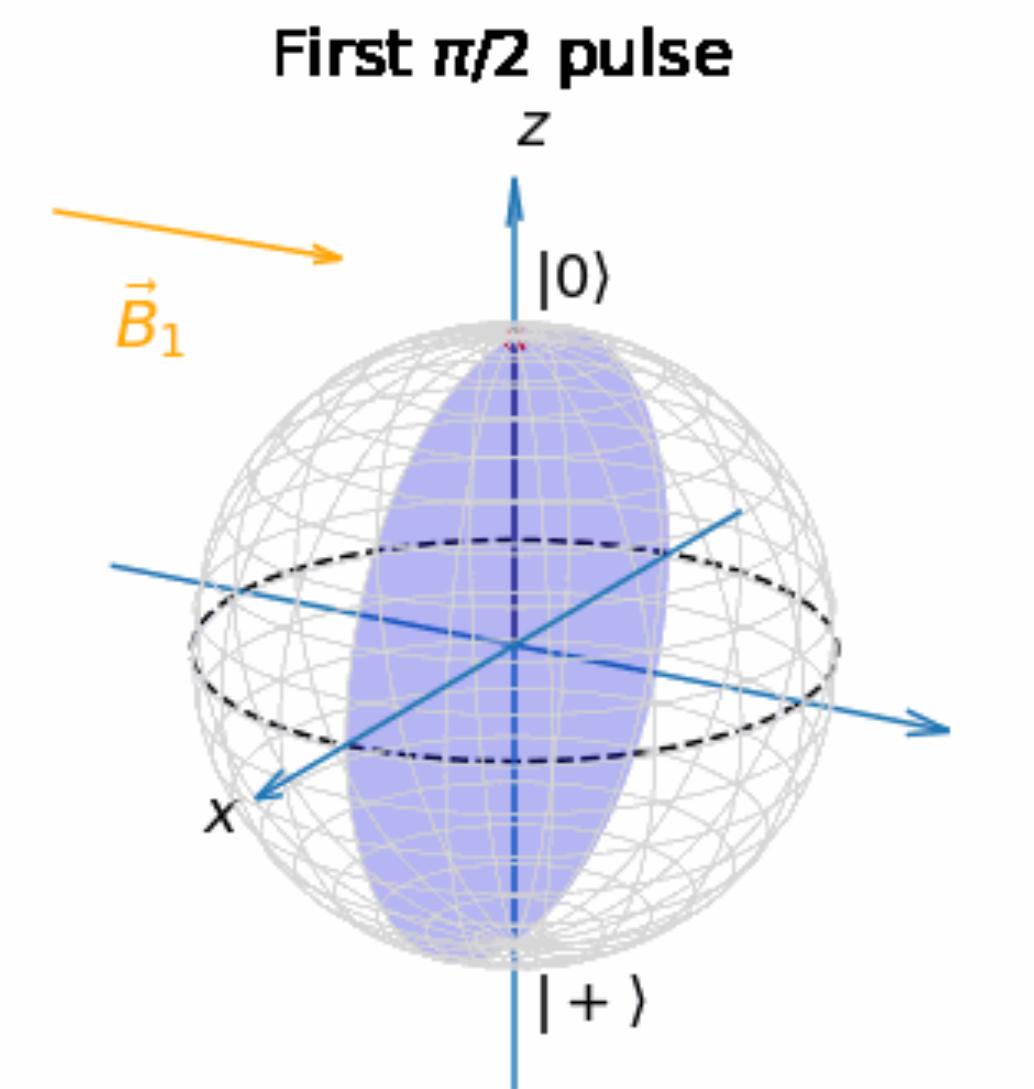

- ▶ (Roughly) flat sensitivity obtained for  $m \lesssim 2\pi/\tau \sim 10^{-8}$  eV

# AC magnetometry

# Ramsey not suitable for AC

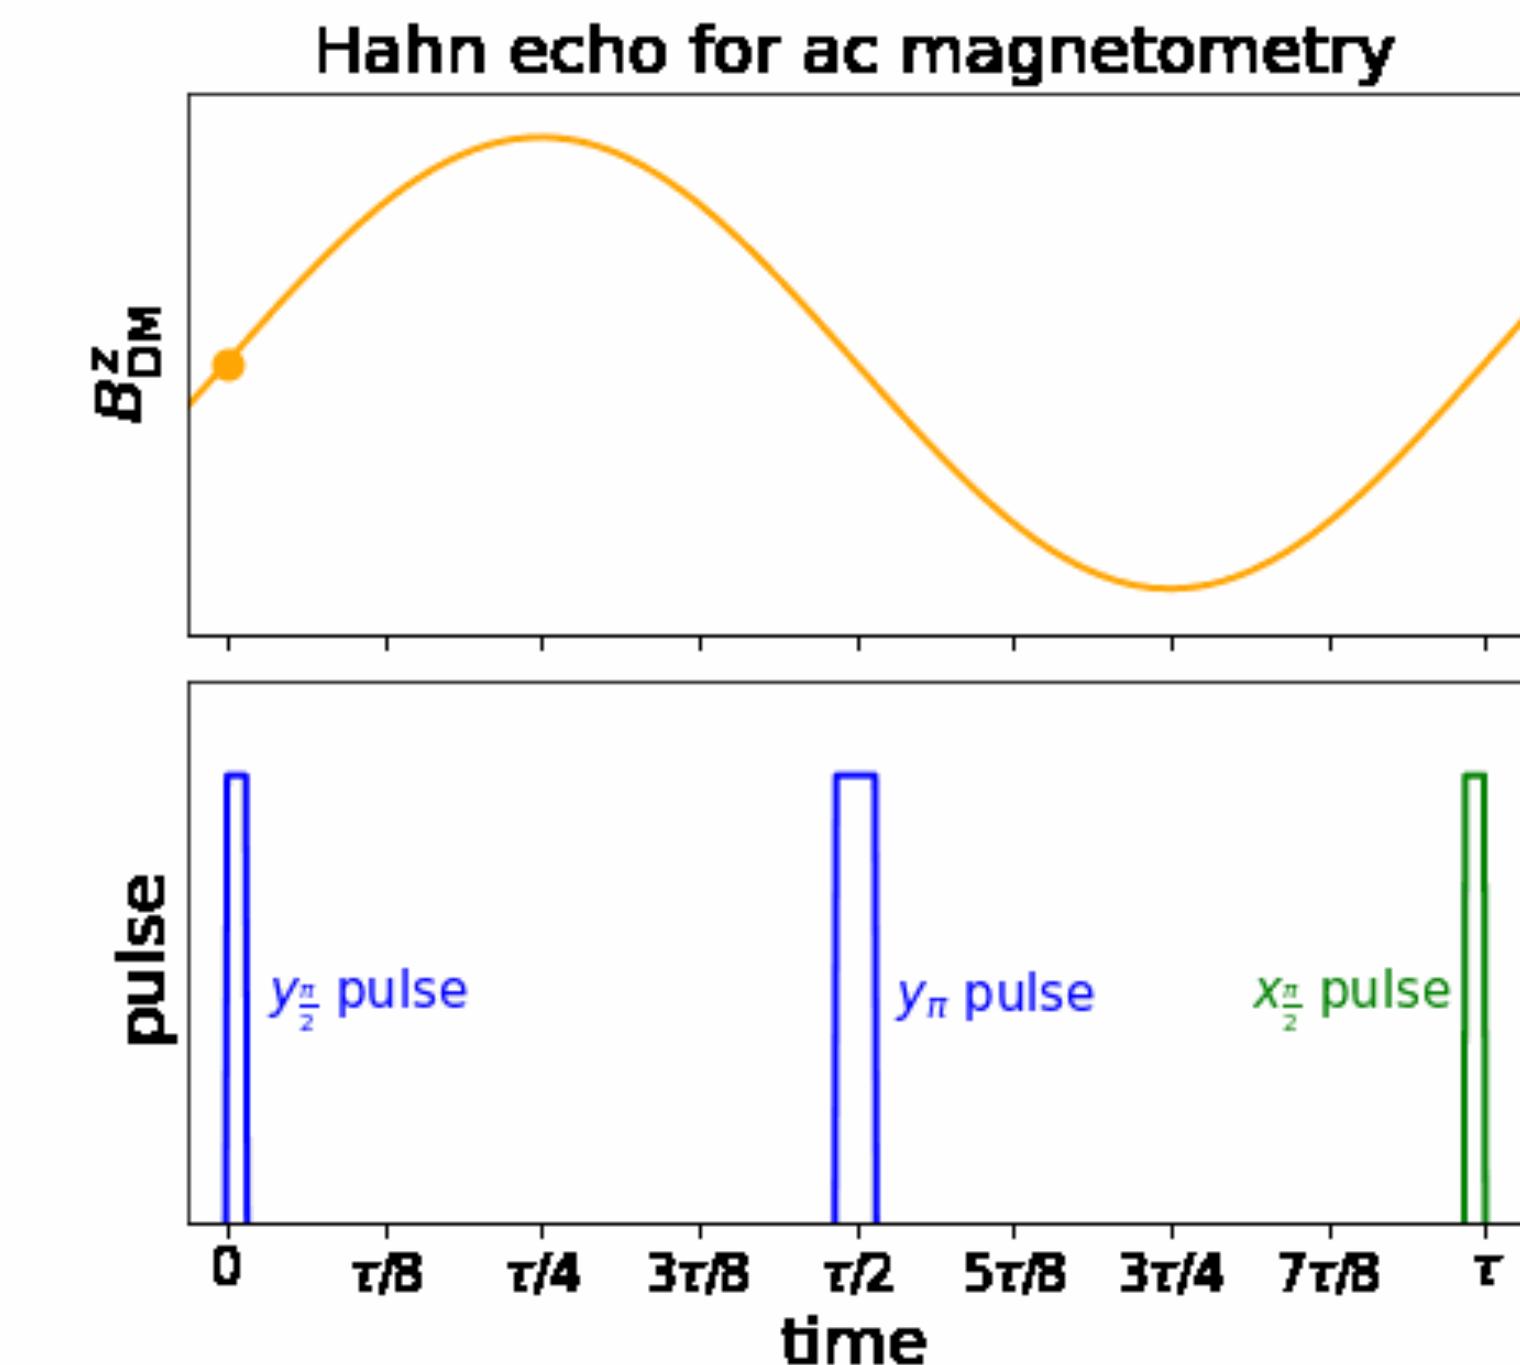

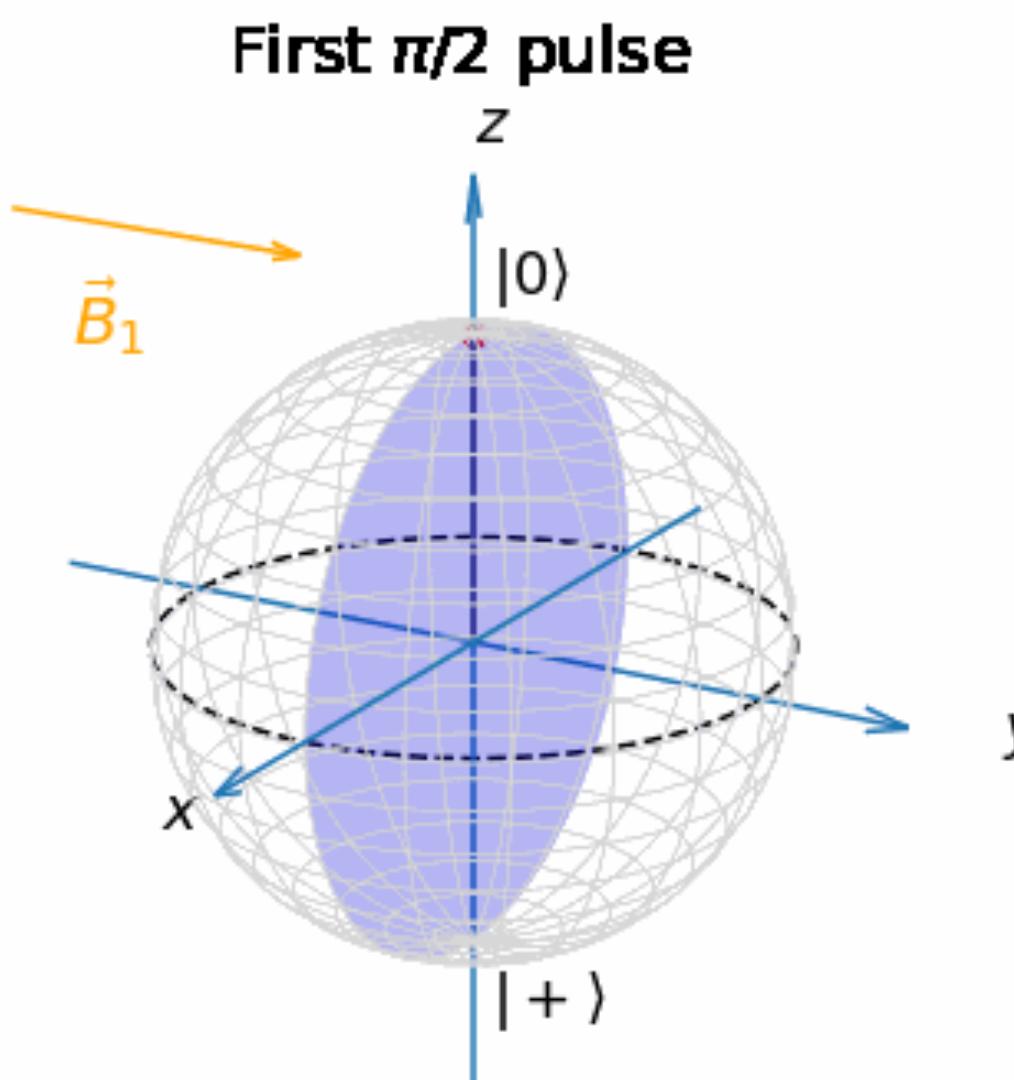

- Fast oscillation leads to cancellation  
when  $m \lesssim 2\pi/\tau$

# Hahn echo

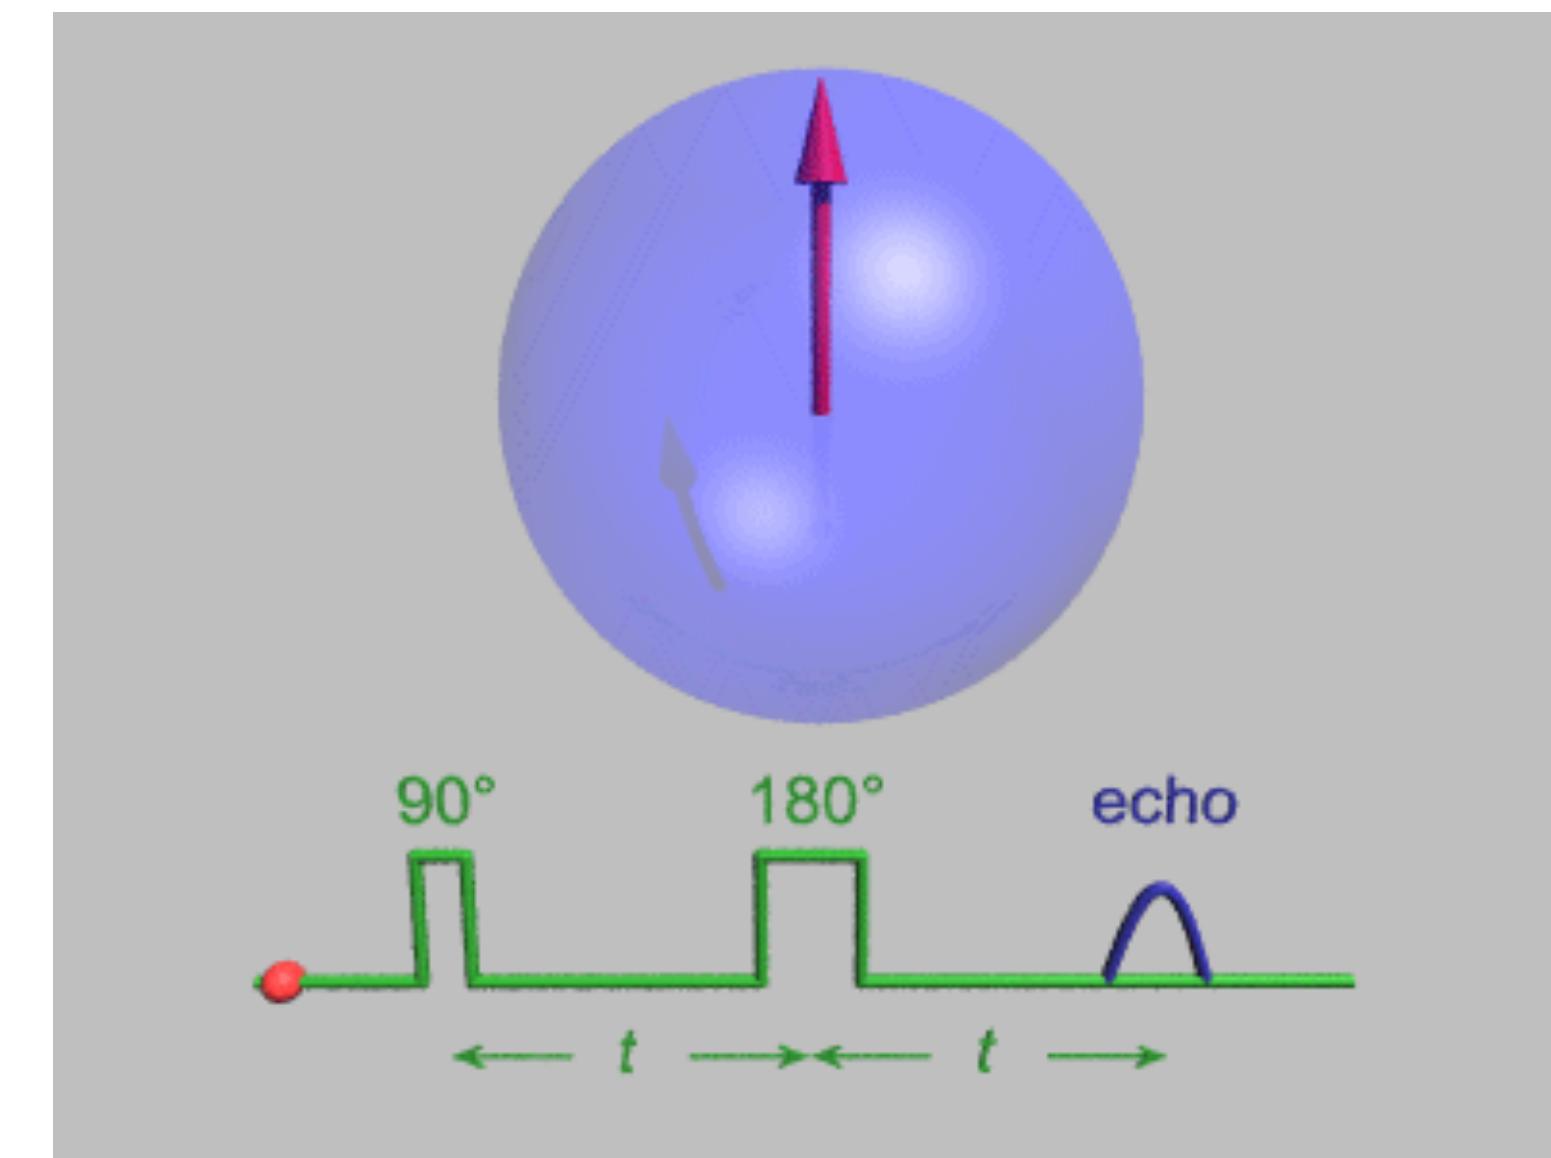

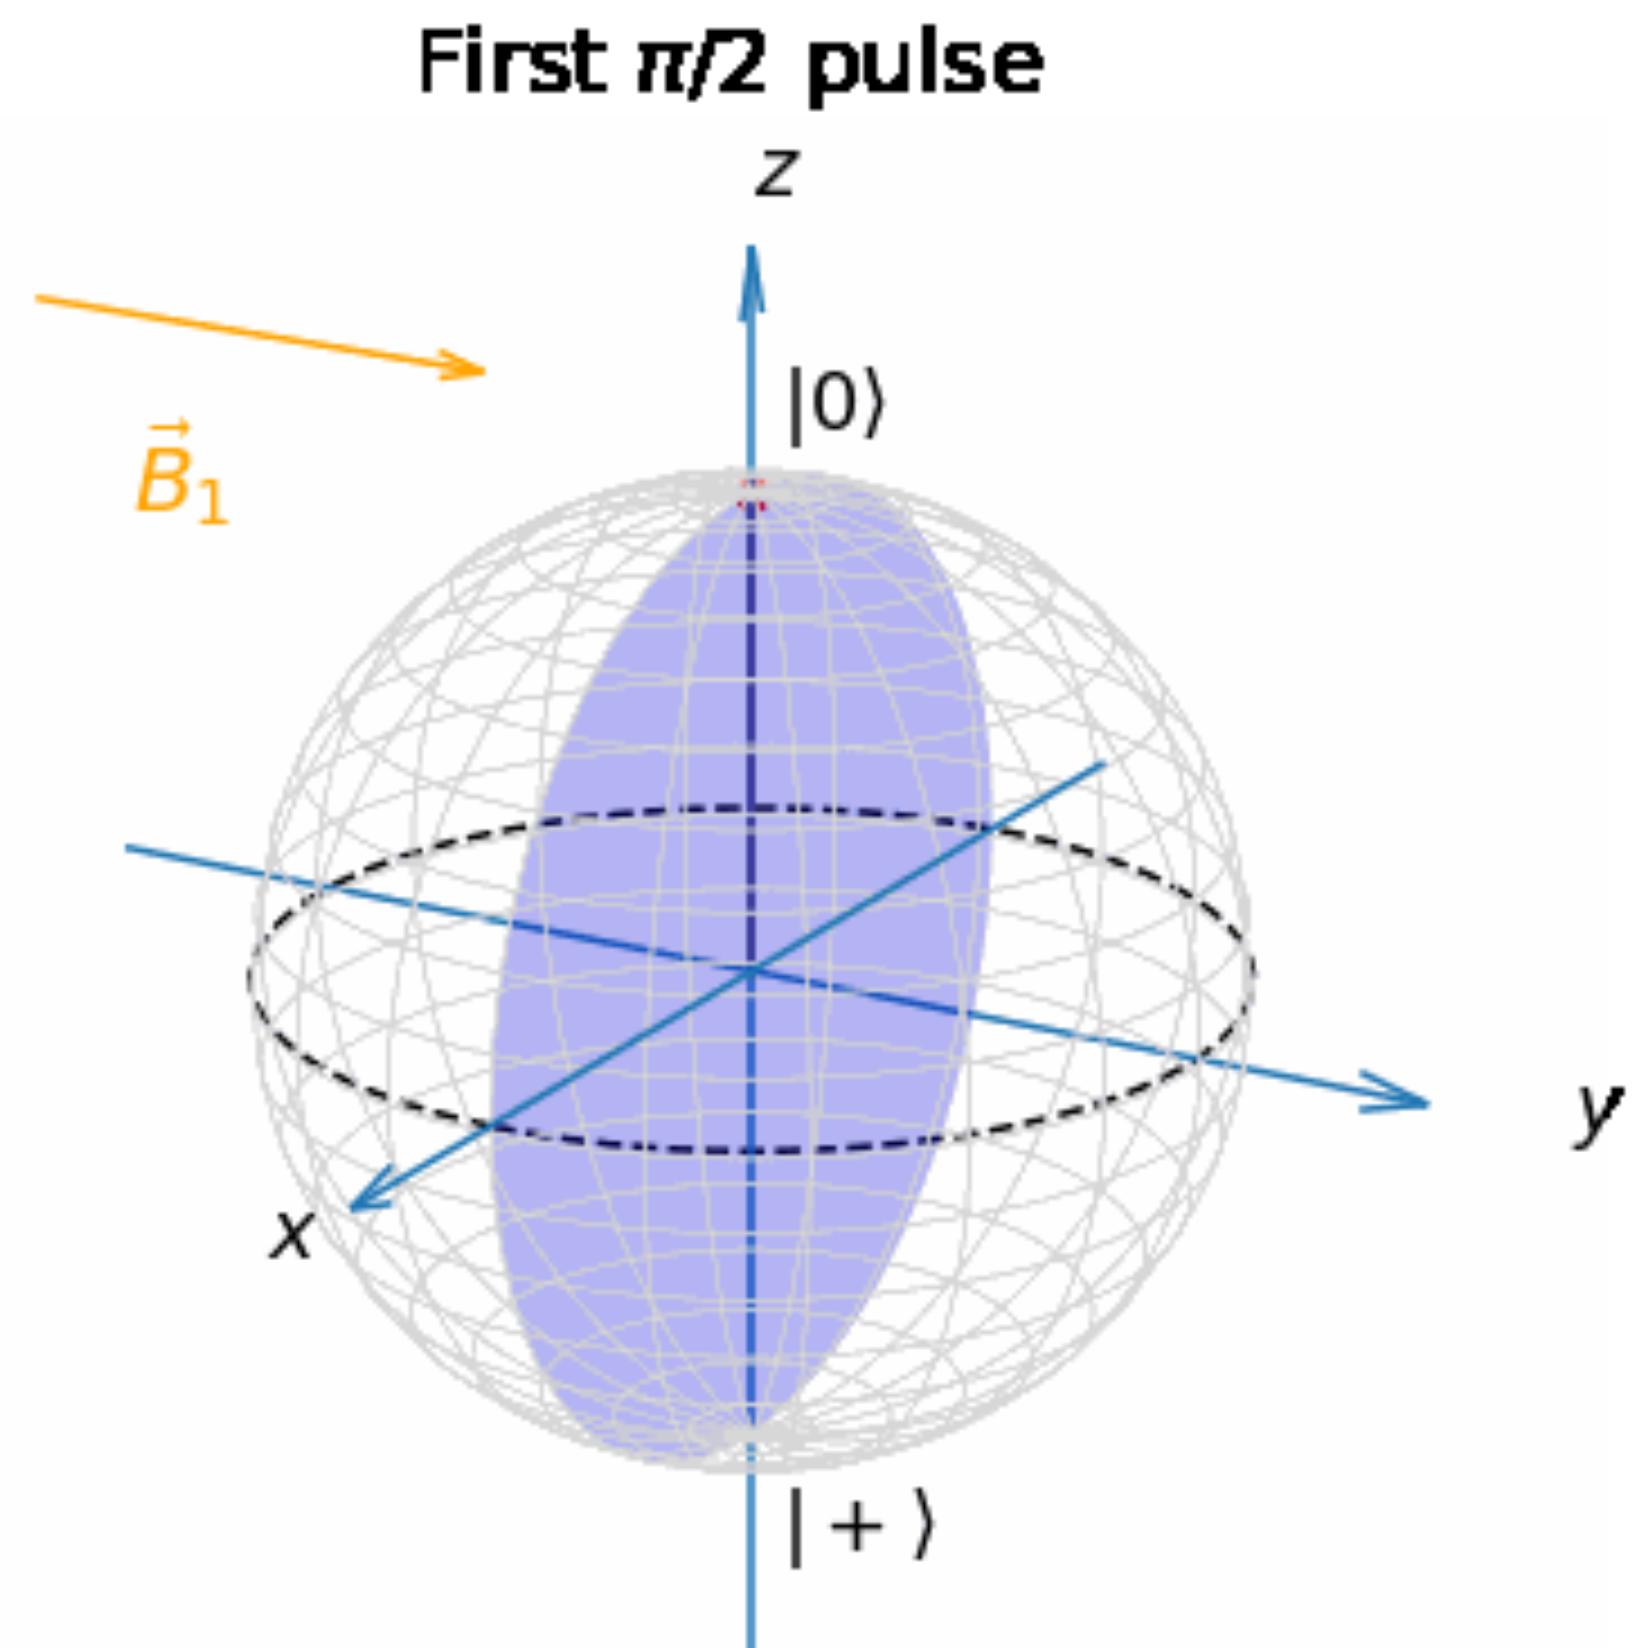

## Hahn echo for AC magnetometry

1.  $(\pi/2)_y$  pulse
2. Free precession for  $\tau/2$
3.  $\pi_y$  pulse
4. Free precession for  $\tau/2$
5.  $(\pi/2)_x$  pulse
6. Fluorescence measurement

$$\varphi(\tau) = \gamma_e \left( \int_0^{\tau/2} dt B_{\text{DM}}^z(t) - \int_{\tau/2}^{\tau} dt B_{\text{DM}}^z(t) \right) \rightarrow \text{Targeted at the frequency } \sim 1/\tau$$

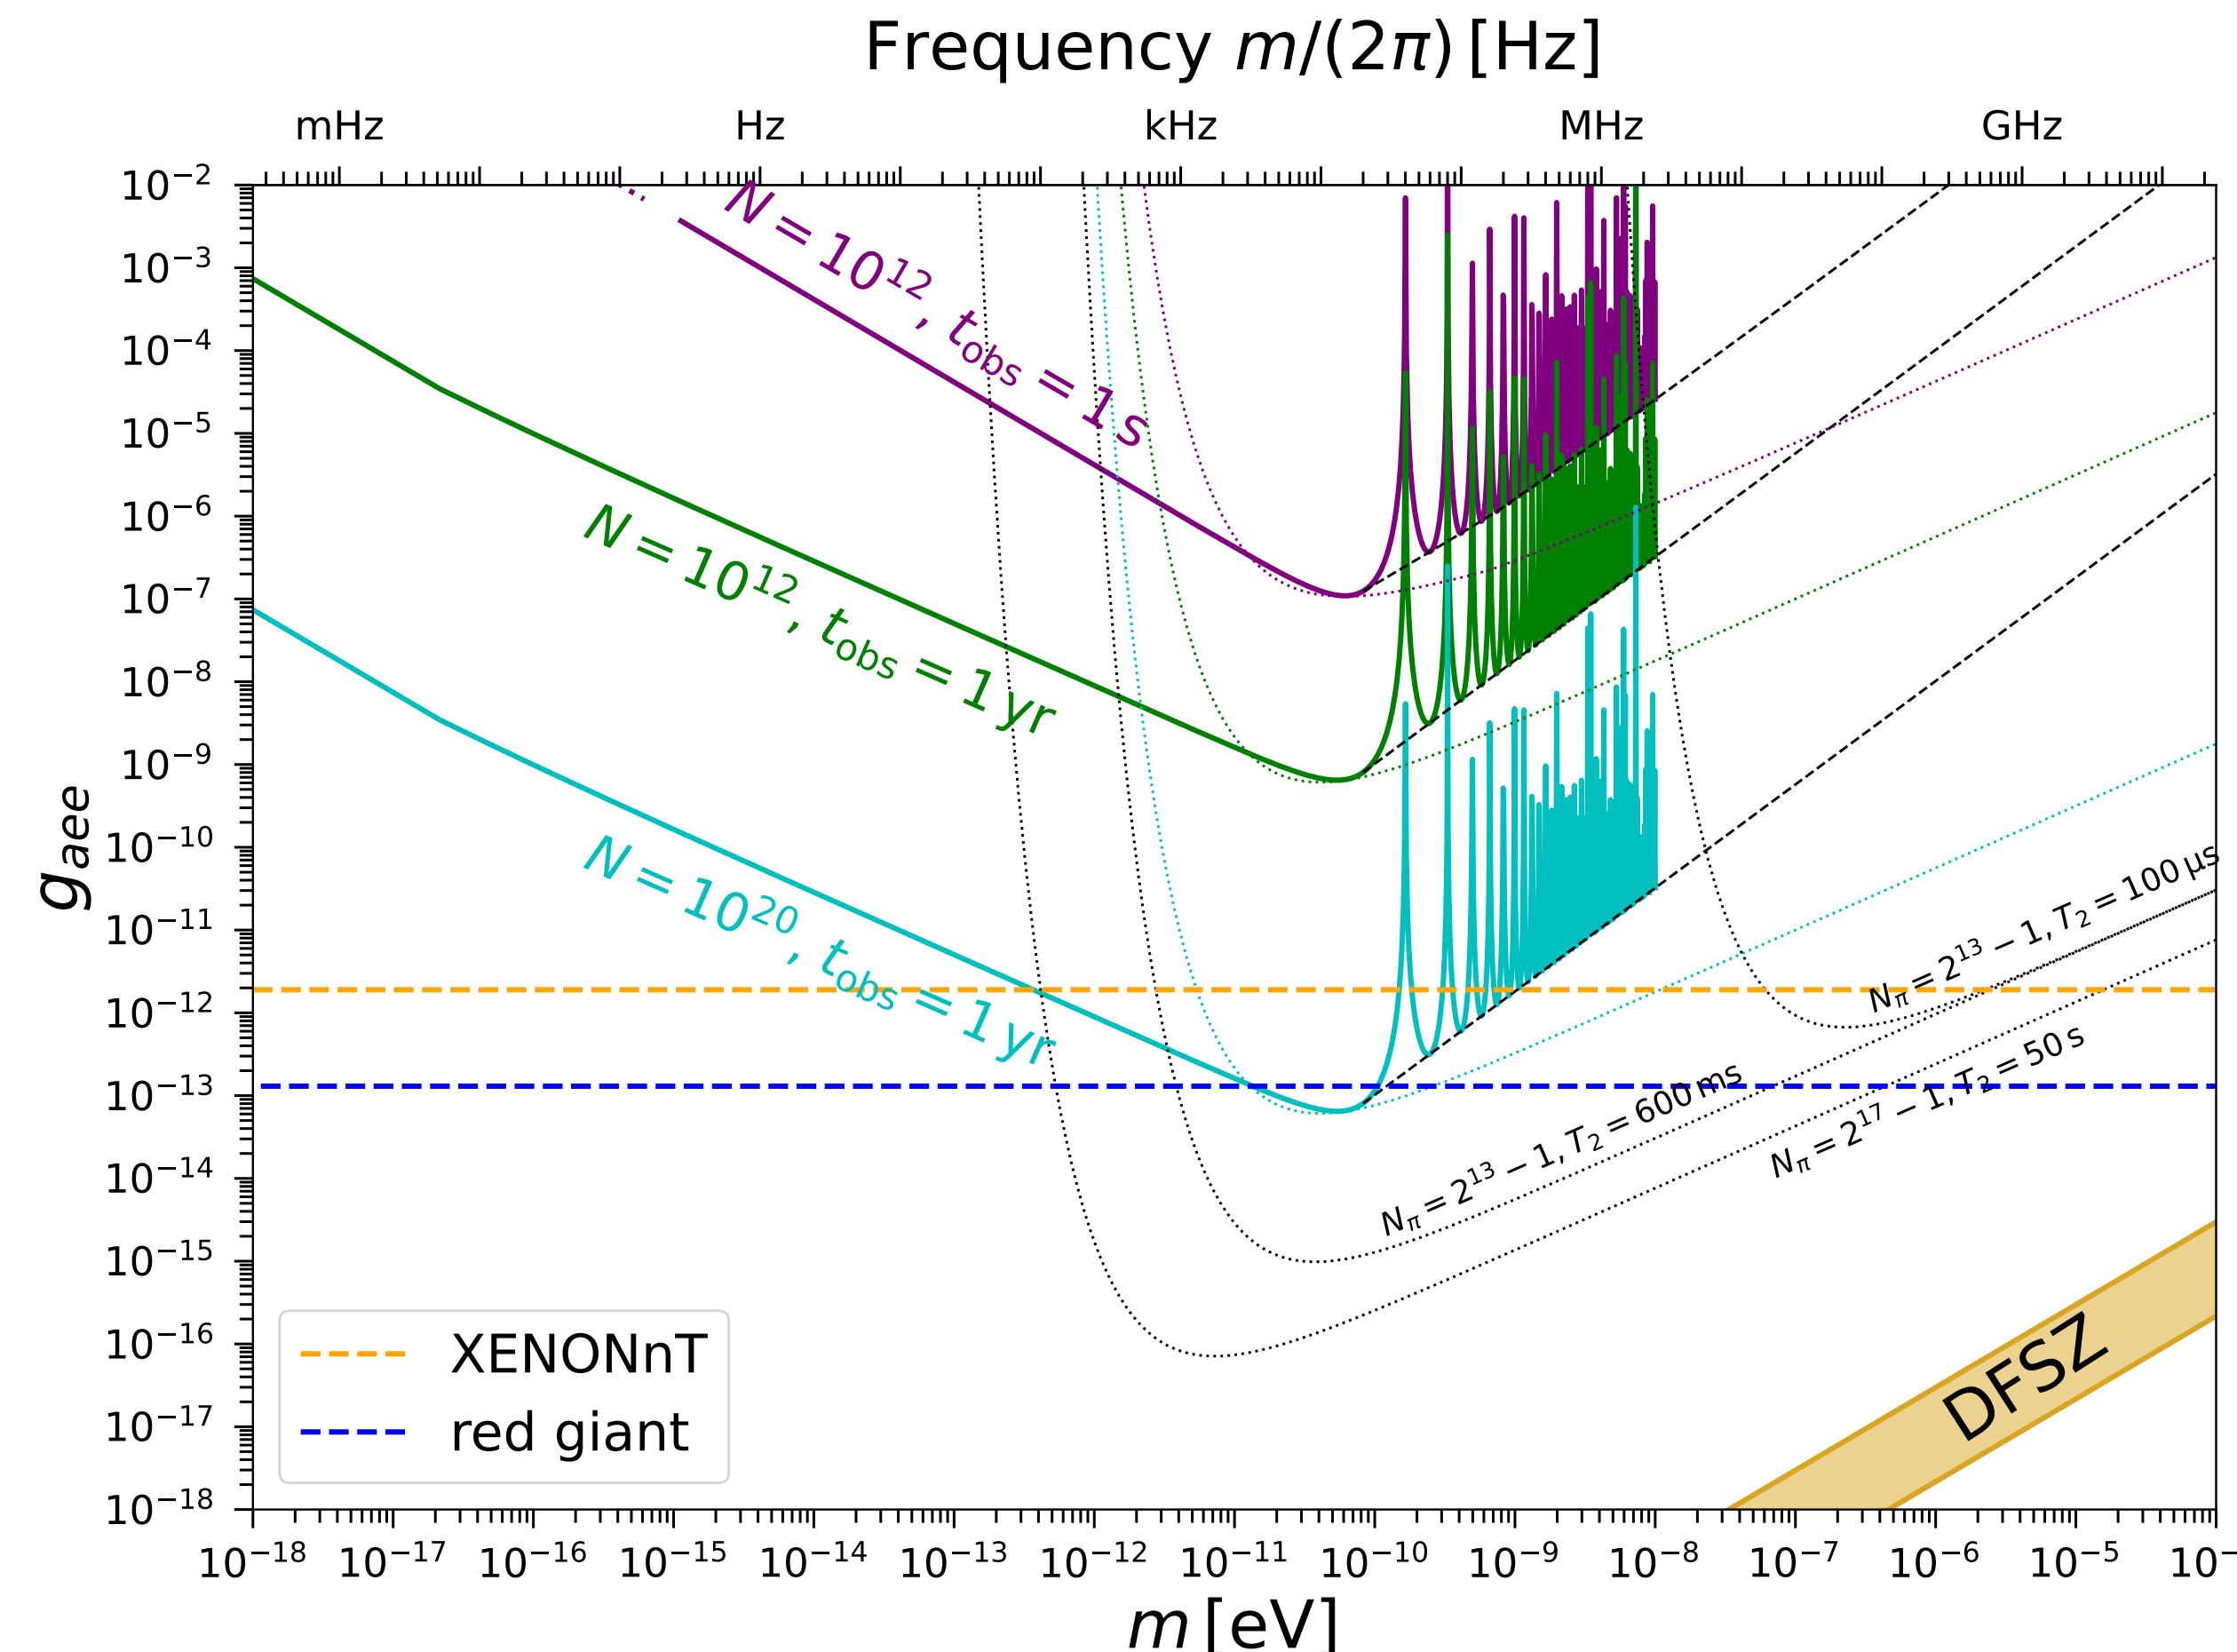

# Prolonged relaxation time

- ▶ Any DC effect cancels out from  $\varphi(t)$
- ▶ No dephasing from inhomogeneous DC fields
- ▶ Relaxation time  $T_2 \sim 50 \mu\text{s} \gg T_2^* \sim 1 \mu\text{s}$
- ▶ Optimized choice  $\tau \sim T_2/2$

# Sensitivity on axion DM

- Sensitivity curve peaked at  $m/2\pi \sim 1/\tau \sim 20 \text{ kHz}$

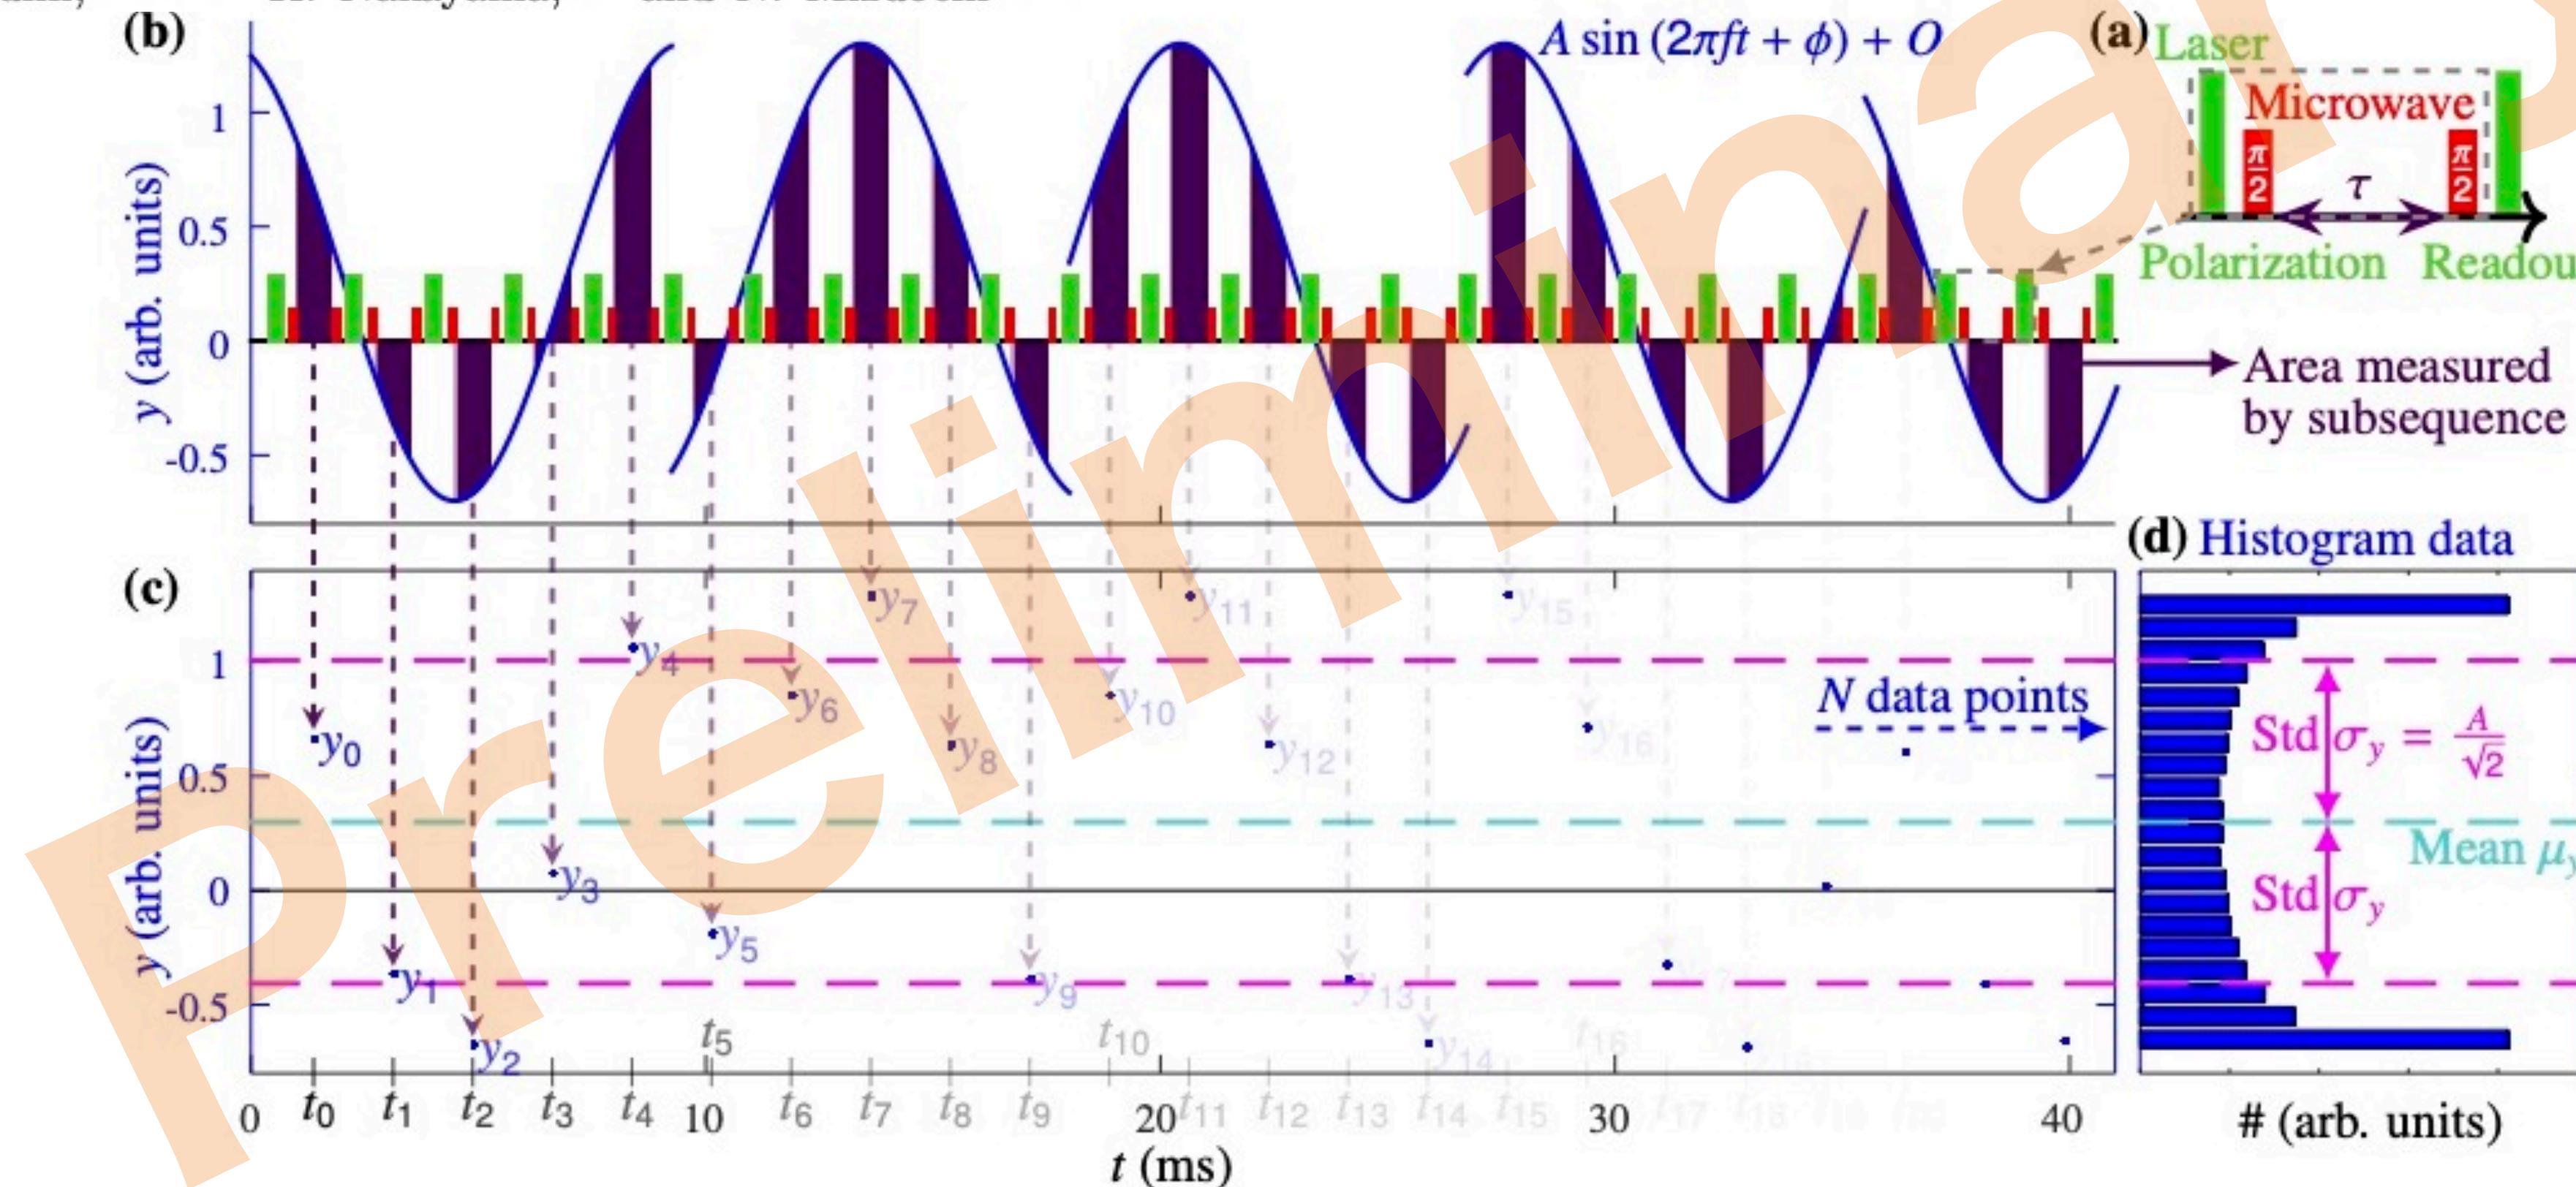

# Experimental status

# Standard-deviation quantum sensing

- Working on experimental validation of our statistical treatment

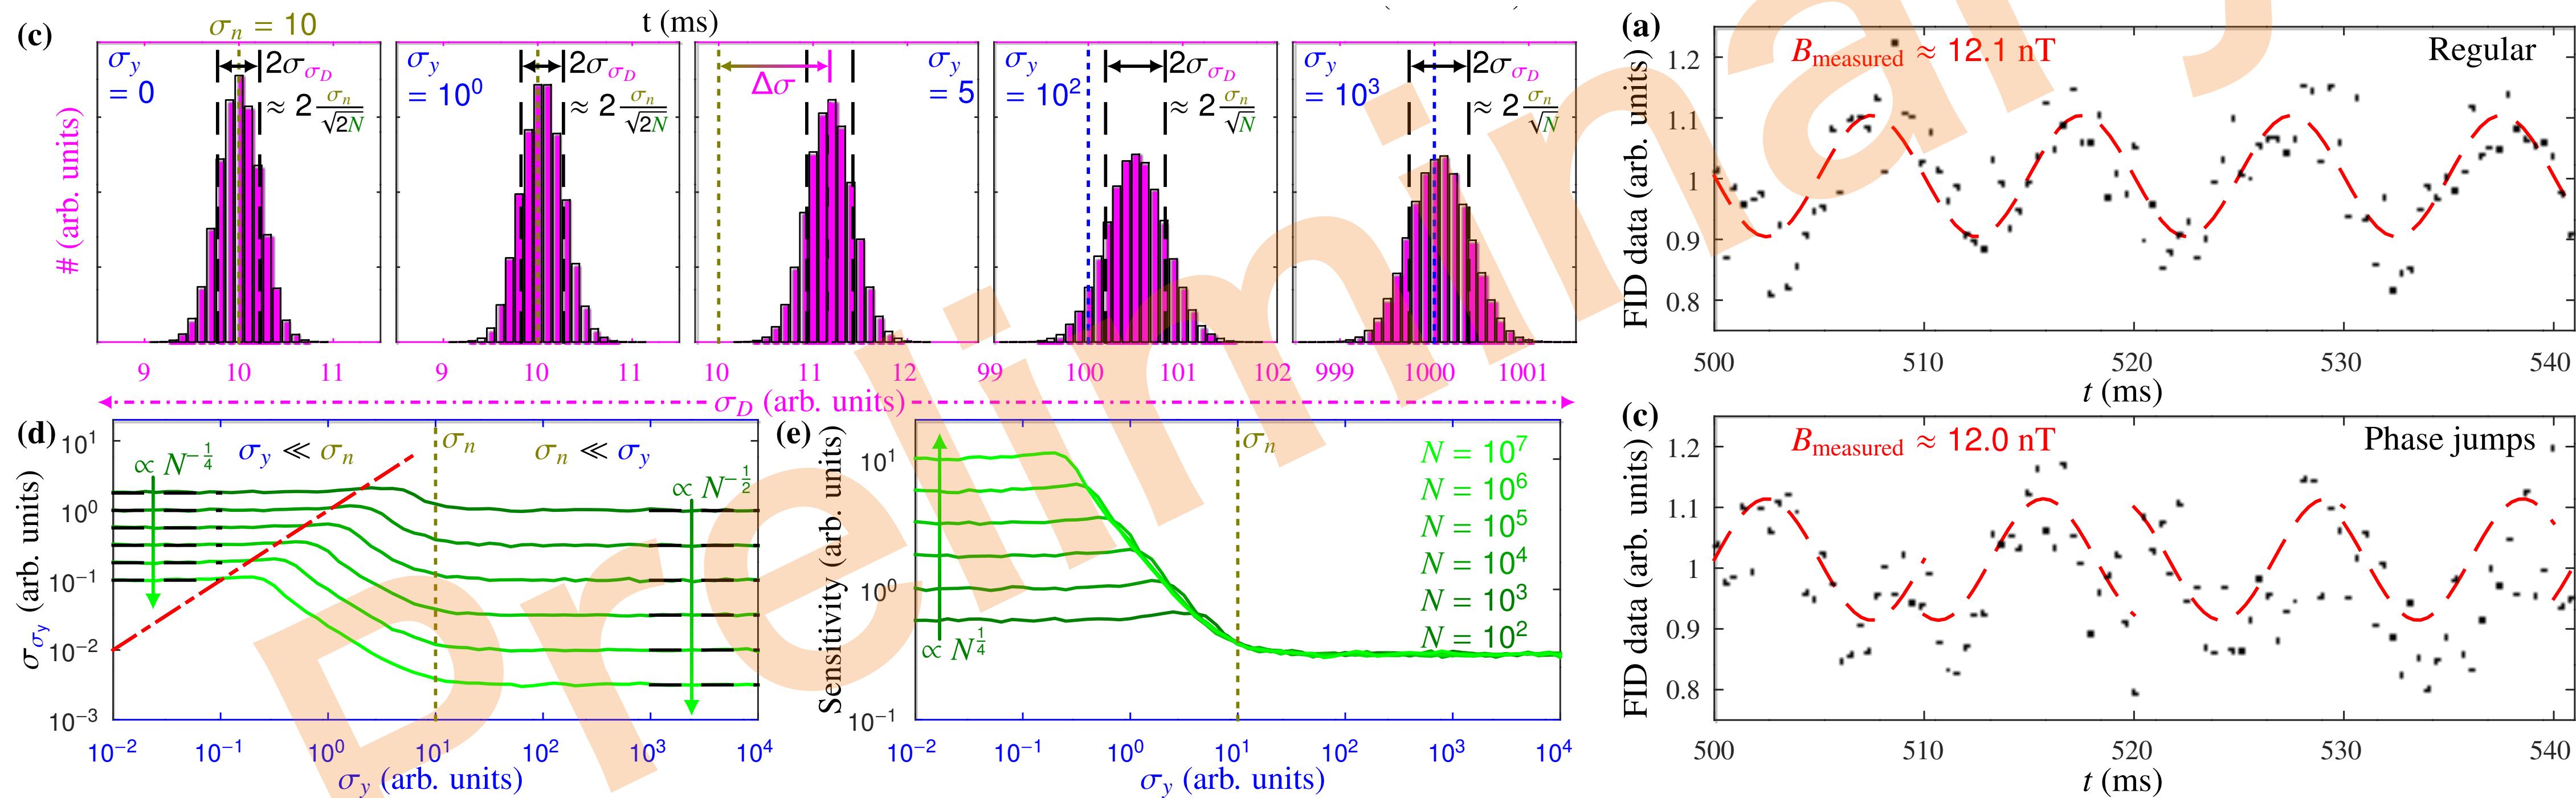

## Standard-deviation quantum sensing

E. D. Herbschleb,<sup>1,\*</sup> S. Chigusa,<sup>2,3</sup> R. Kawase,<sup>1</sup> H. Kawashima,<sup>1</sup>  
M. Hazumi,<sup>4,5,6,7,8</sup> K. Nakayama,<sup>9,4</sup> and N. Mizuochi<sup>1,10,4</sup>

# Standard-deviation quantum sensing

- Obtained expected dependence on # of data points  $N$
- Can estimate signal amplitude and frequency

# Discussion & conclusion

# Quantum metrology

- ▶ Possible application of involved quantum metrology techniques to NV center

- ▶ Example: use of entanglement

- Transmon qubit

S. Chen+ [2311.10413]

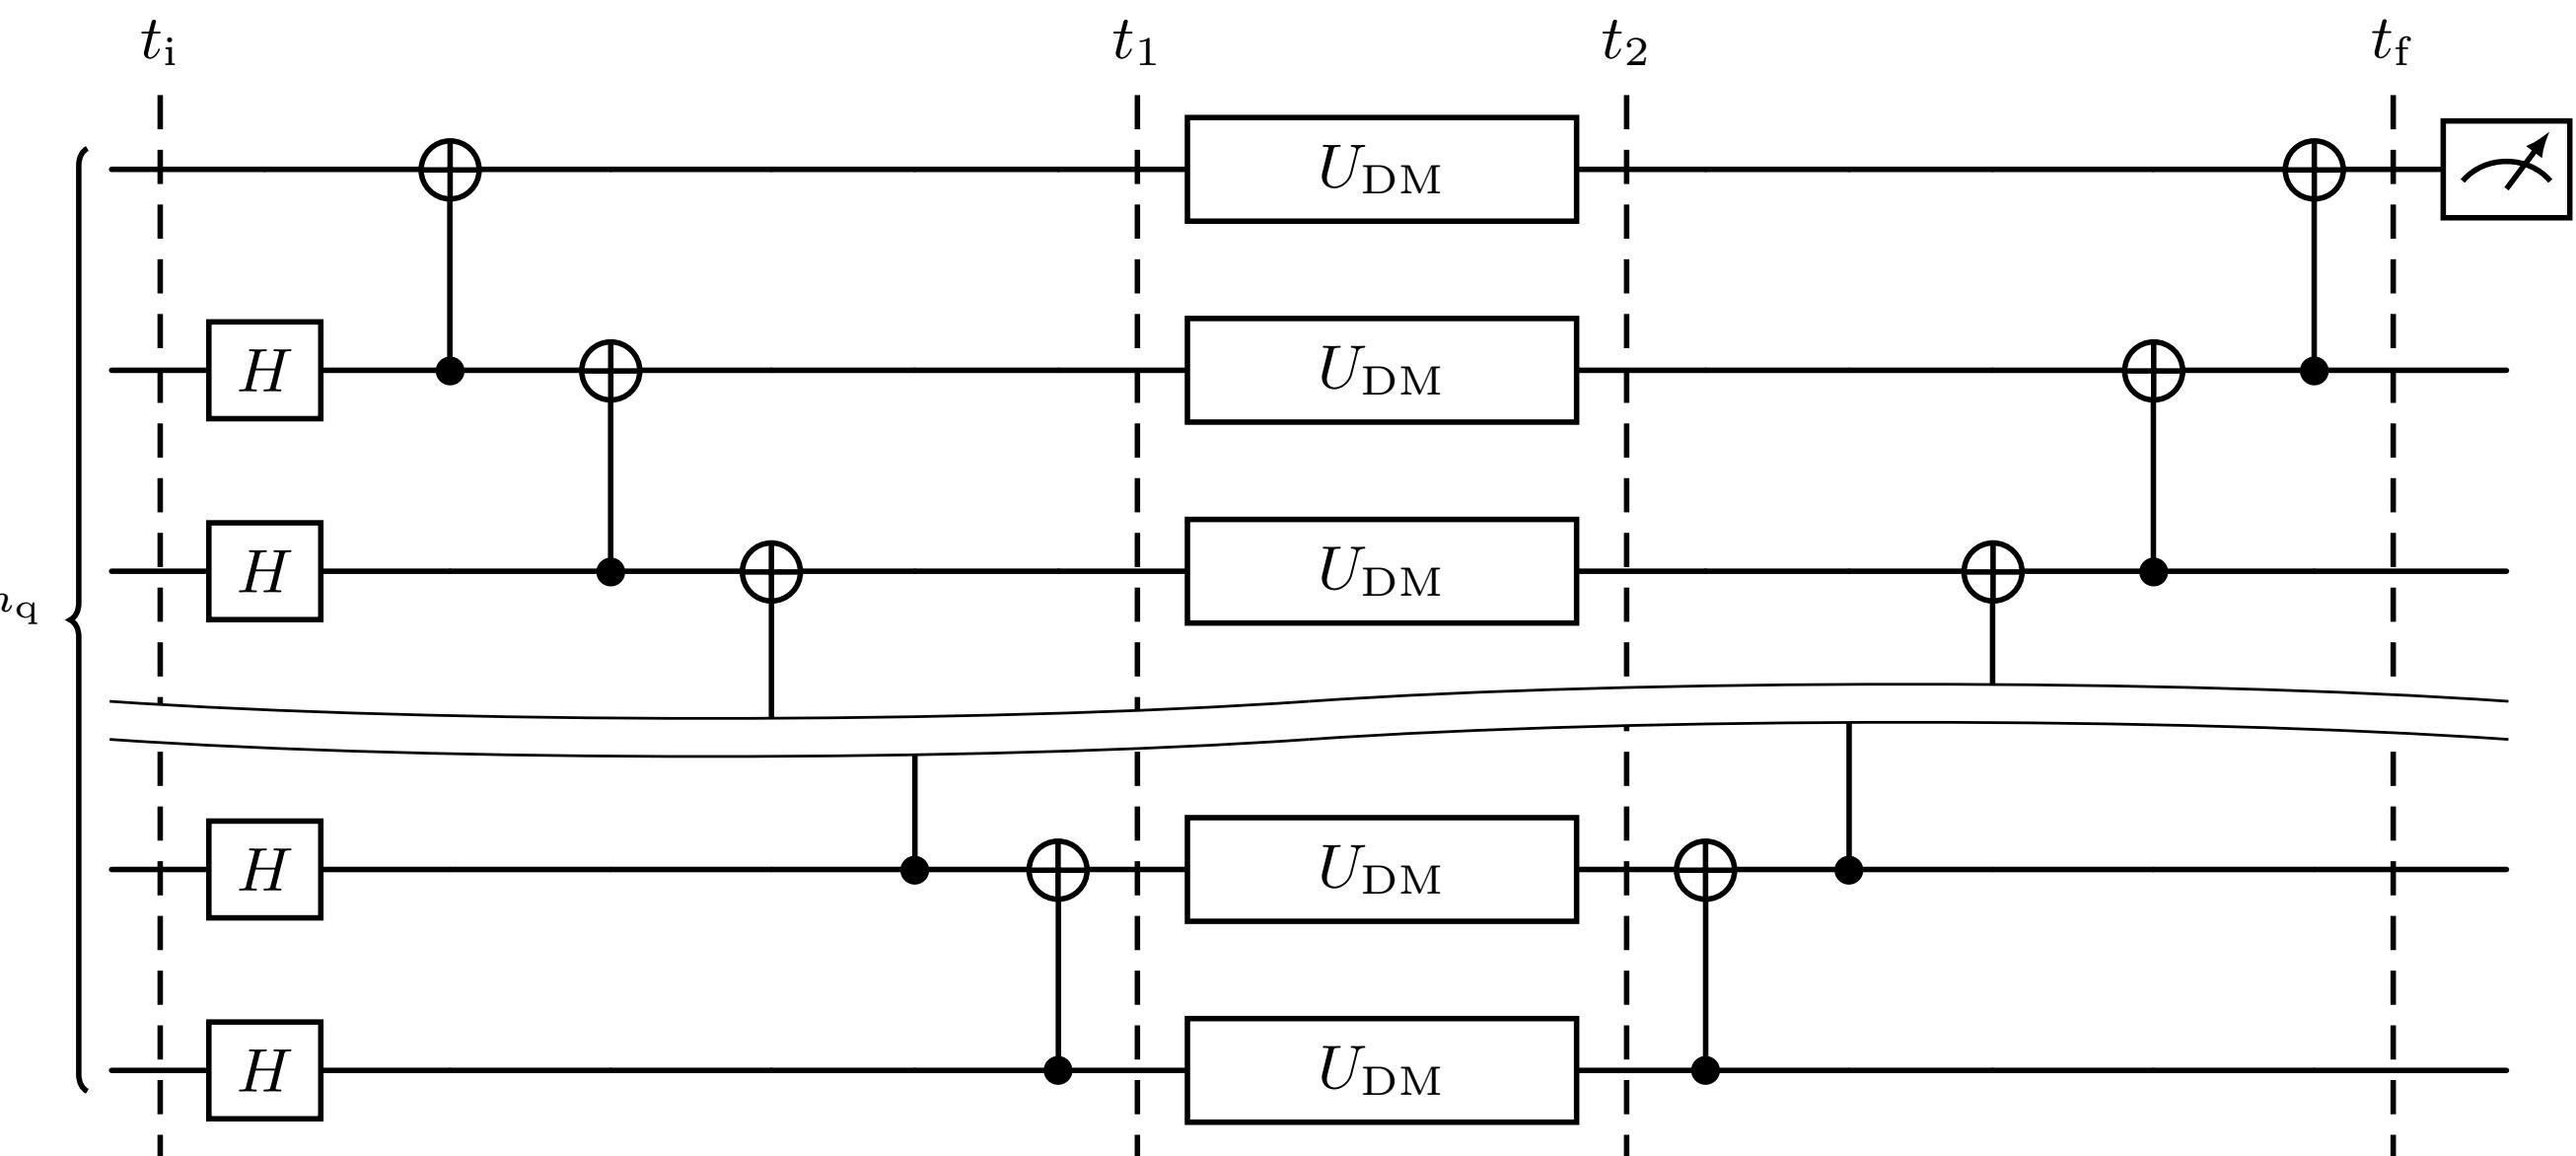

- Paul ion trap

A. Ito+ [2311.11632]

- ▶  $|\psi\rangle = \bigotimes_c \frac{1}{\sqrt{2}}(|0\rangle_c + e^{i\varphi} |1\rangle_c)$

$$\rightarrow |\psi\rangle = \frac{1}{\sqrt{2}} (|0\rangle^{\otimes N} + e^{iN\varphi} |1\rangle^{\otimes N})$$

sensors,  $|g\rangle^{\otimes n_q}$

- ▶  $\times N$  gain at the level of amplitude,  $\times N^2$  gain of signal

C. L. Degan+ “Quantum sensing” for review

# Conclusion

- ▶ We explored the potential of NV center magnetometry for DM search
- ▶ Benefits of this approach include:
  - Wide dynamic range = broad DM mass range is searched for
  - Not always need magnetic shielding
- ▶ Some applications of involved quantum metrology techniques are possible
  - e.g.) Use of entanglement
- ▶ Now setting up an experimental environment at QUP with NV + cryogenic

# Sensitivity estimation

- ▶ The outcome of the spin-projection noise

$$|x\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle + |+\rangle)$$

$$\Delta S \equiv \frac{1}{2} \left[ \langle x | \sigma_z^2 | x \rangle - (\langle x | \sigma_z | x \rangle)^2 \right]^{1/2} = \frac{1}{2}$$

- ▶ Noise contribution is  $\Delta S_{\text{sp}} \sim \begin{cases} \frac{1}{2} \frac{1}{\sqrt{N(t_{\text{obs}}/\tau)}} & (t_{\text{obs}} < \tau_a) \\ \frac{1}{2} \frac{1}{\sqrt{N(\tau_a/\tau)}} \frac{1}{(t_{\text{obs}}/\tau_a)^{1/4}} & (t_{\text{obs}} > \tau_a) \end{cases}$
- ▶ Sensitivity curve is  $(\text{SNR}) \equiv \frac{S}{\Delta S_{\text{sp}}} = 1$

# Sensitivity estimation

- ▶ The axion-induced effective magnetic field has an unknown velocity  $\mathbf{v}_{\text{DM}}$  and phase  $\delta$

$$\mathbf{B}_{\text{DM}} \simeq \sqrt{2\rho_{\text{DM}}} \frac{g_{aee}}{e} \mathbf{v}_{\text{DM}} \sin(m_{\text{DM}} t + \delta)$$

Random velocity  $\mathbf{v}_{\text{DM}}$

- ▶ The signal is proportional to  $(v_{\text{DM}}^i)^2$  ( $i = x, y, z$ ), which is averaged to  $\sim \frac{1}{3} v_{\text{DM}}^2$

Random phase  $\delta \in [0, 2\pi)$

- ▶ The signal is estimated as a function of  $\delta$  :  $S(\delta) \propto \cos\left(\frac{m\tau}{2} + \delta\right)$
- ▶ We obtain the average  $\langle S \rangle_\delta = 0$  and the standard deviation  $\sqrt{\langle S^2 \rangle} \neq 0$ , which should be compared with the noise

# Effects of DM coherence time

- $B_{\text{DM}}^z$  and  $\delta$  change randomly with  $\tau_{\text{DM}} \sim 2\pi/m_{\text{DM}}v_{\text{DM}}^2$

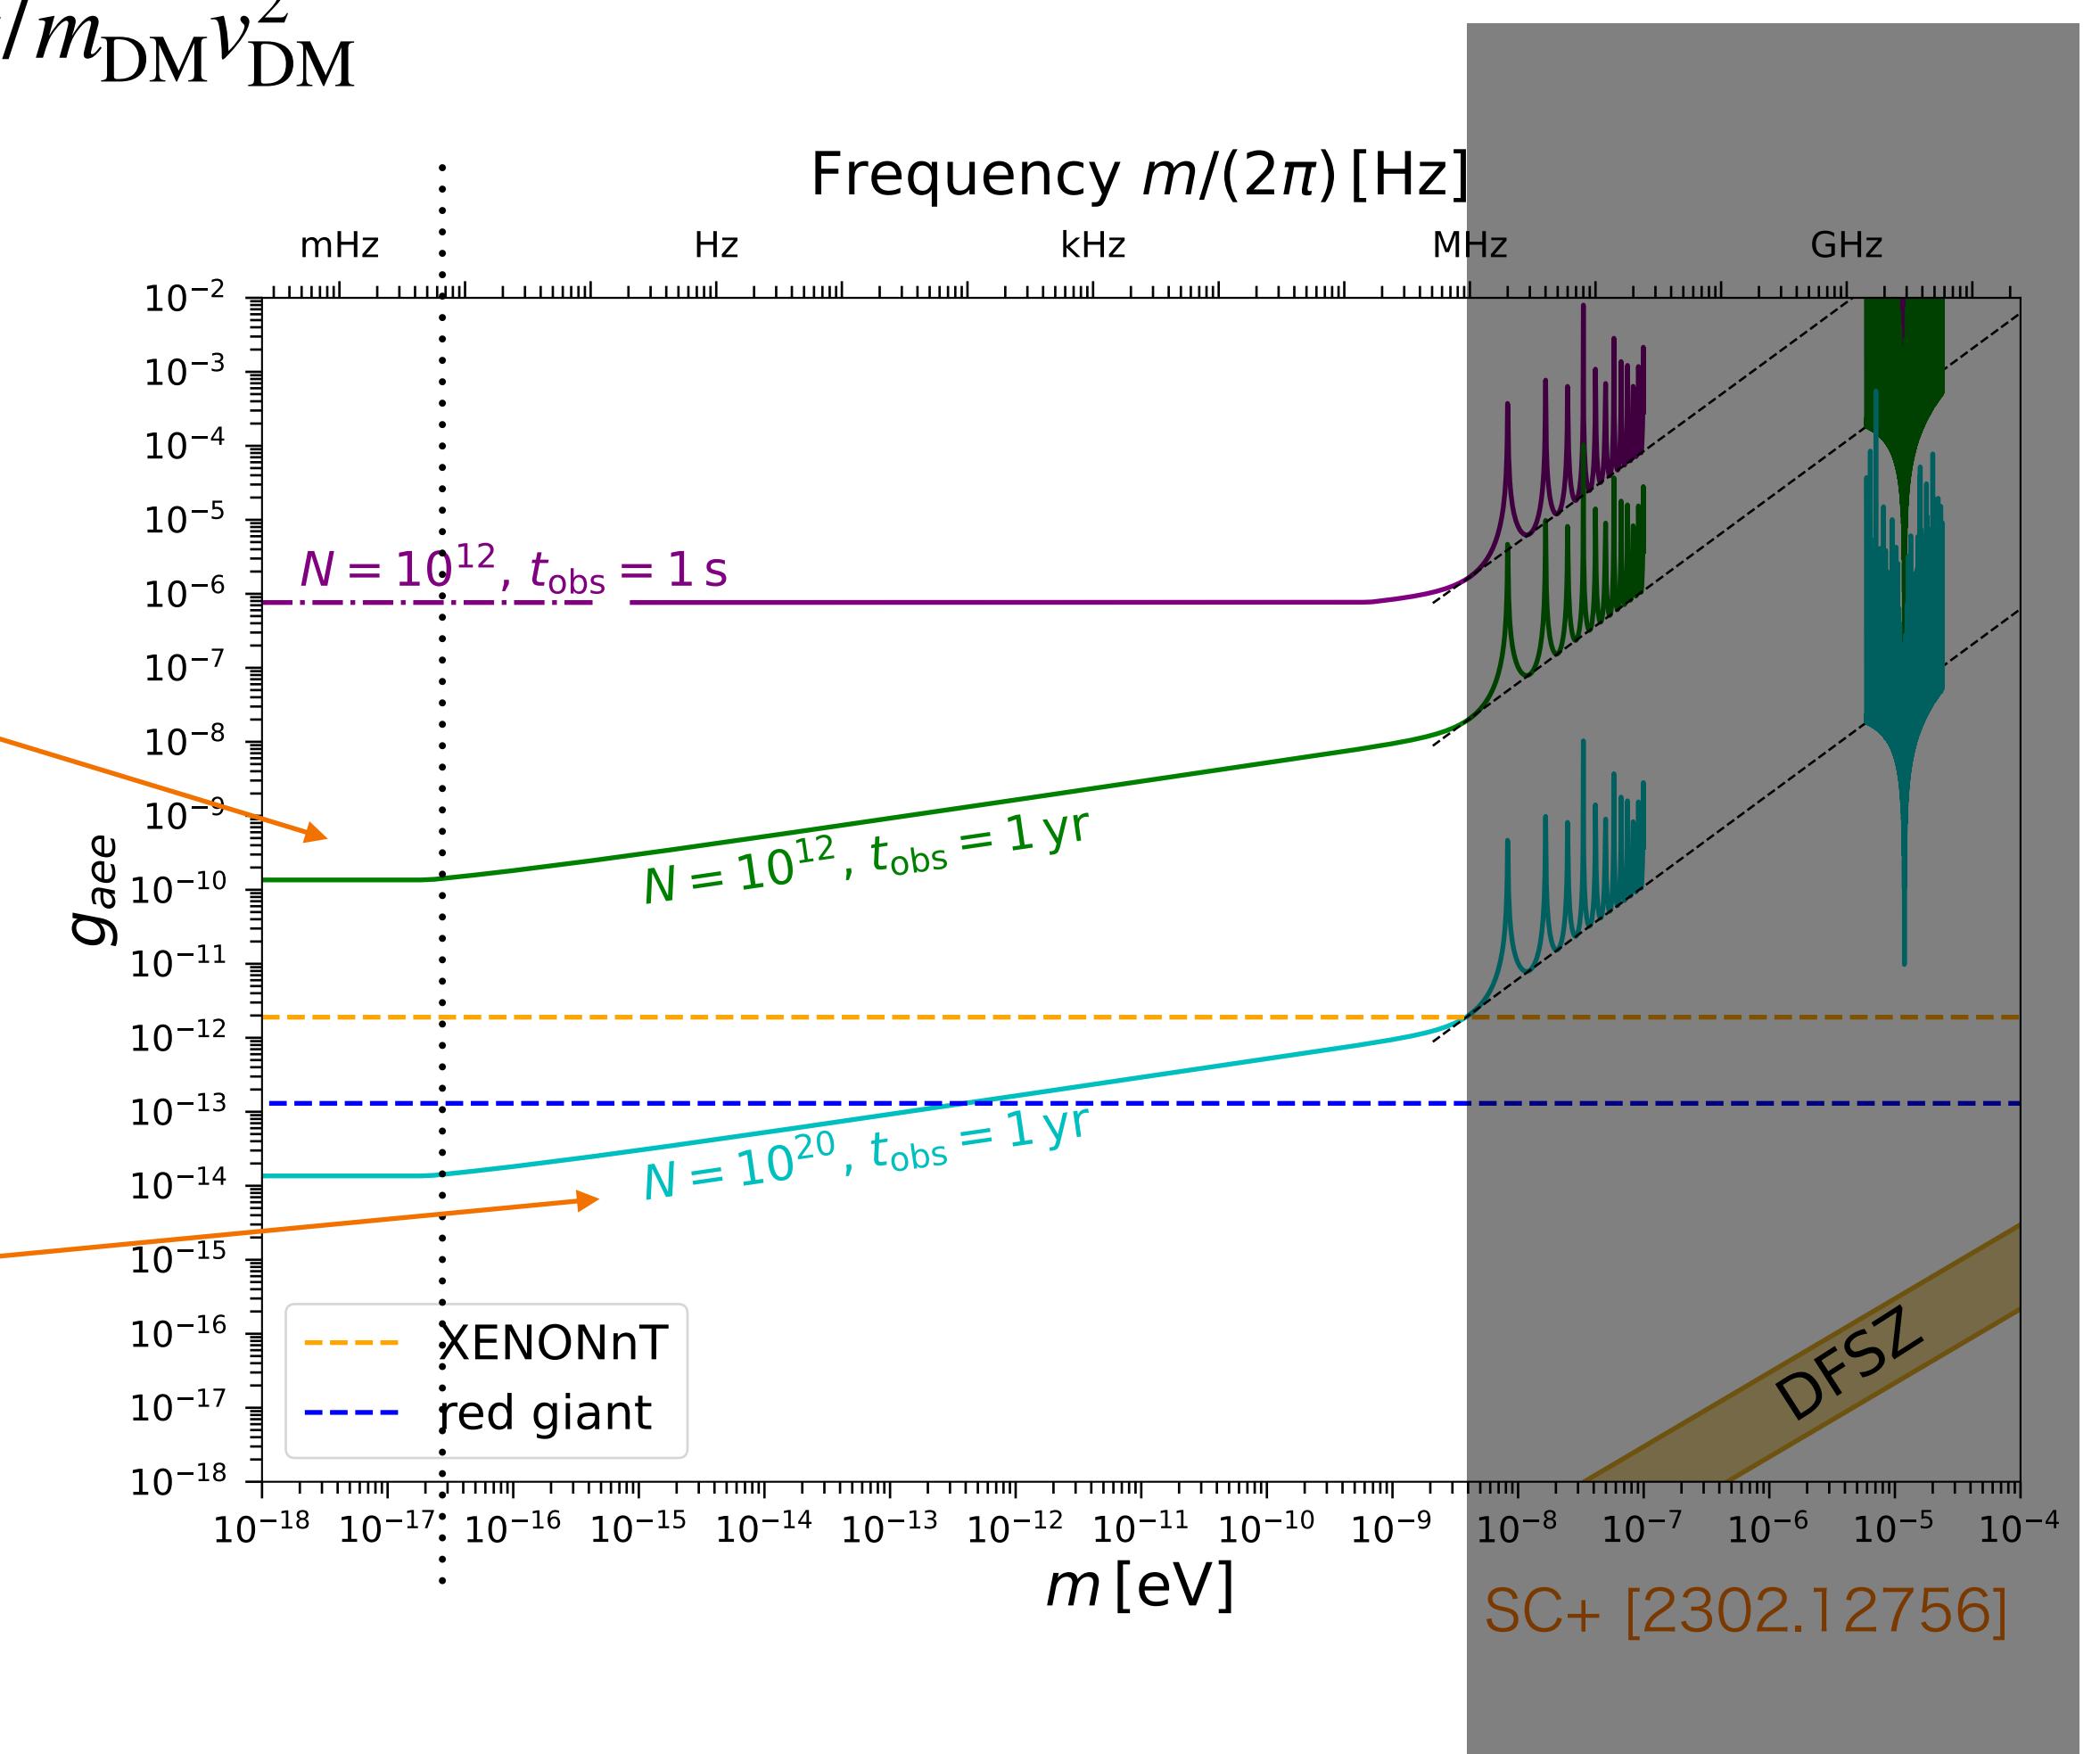

- For  $t_{\text{obs}} \ll \tau_{\text{DM}}$

- Fixed  $B_{\text{DM}}^z$  and  $\delta$
- (<# of observations>)  $\simeq N(t_{\text{obs}}/\tau)$
- (Sensitivity)  $\propto N^{1/2} (t_{\text{obs}}/\tau)^{1/2}$

- For  $t_{\text{obs}} \gg \tau_{\text{DM}}$

- We measure the variance of  $S_{\text{obs}}$
- Comparison of  $\Delta S_{\text{DM}}$  and  $\Delta S N^{-1/2} (\tau_{\text{DM}}/\tau)^{-1/2}$
- (Sensitivity)  $\propto N^{1/2} (\tau_{\text{DM}}/\tau)^{1/2} (t_{\text{obs}}/\tau_{\text{DM}})^{1/4}$

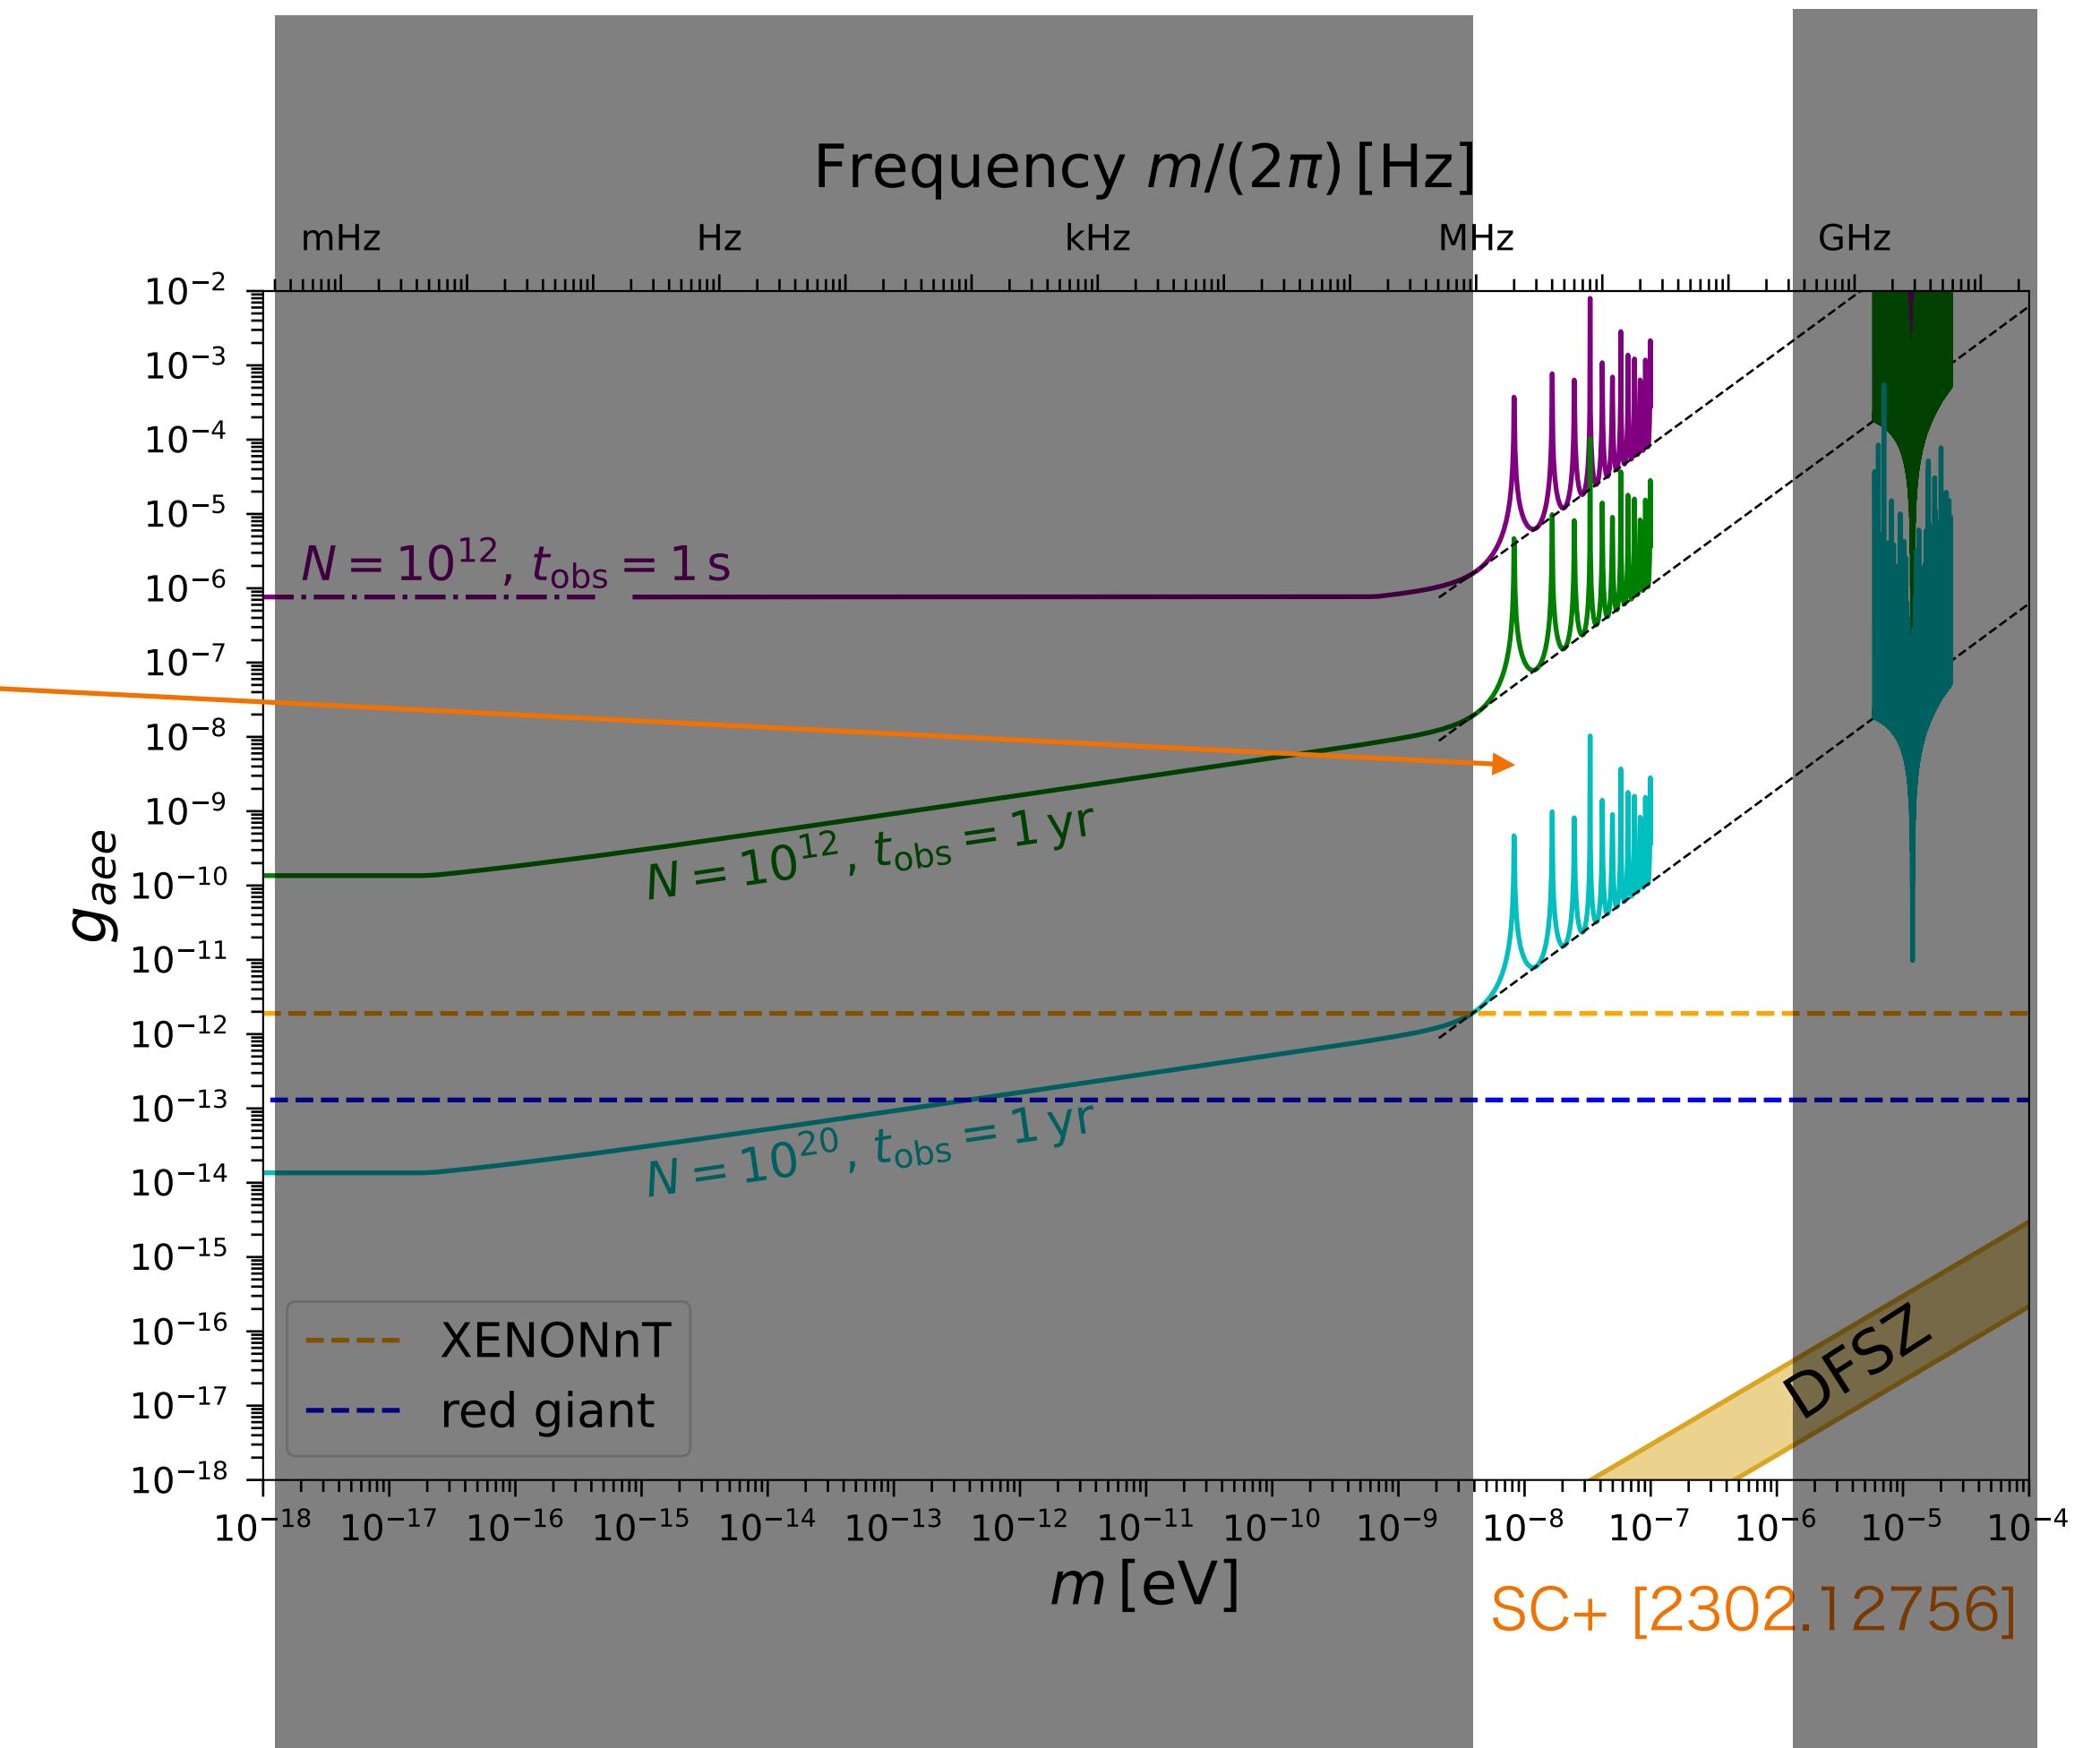

Consistent with Dror+ [2210.06481] in the context of CASPER

# Inensitive to fast-oscillating signals

- Fast oscillation leads to cancellation

$$S \sim \int_0^\tau dt B_{\text{DM}}^z \sin(mt) \propto \frac{1 - \cos(m\tau)}{m\tau}$$

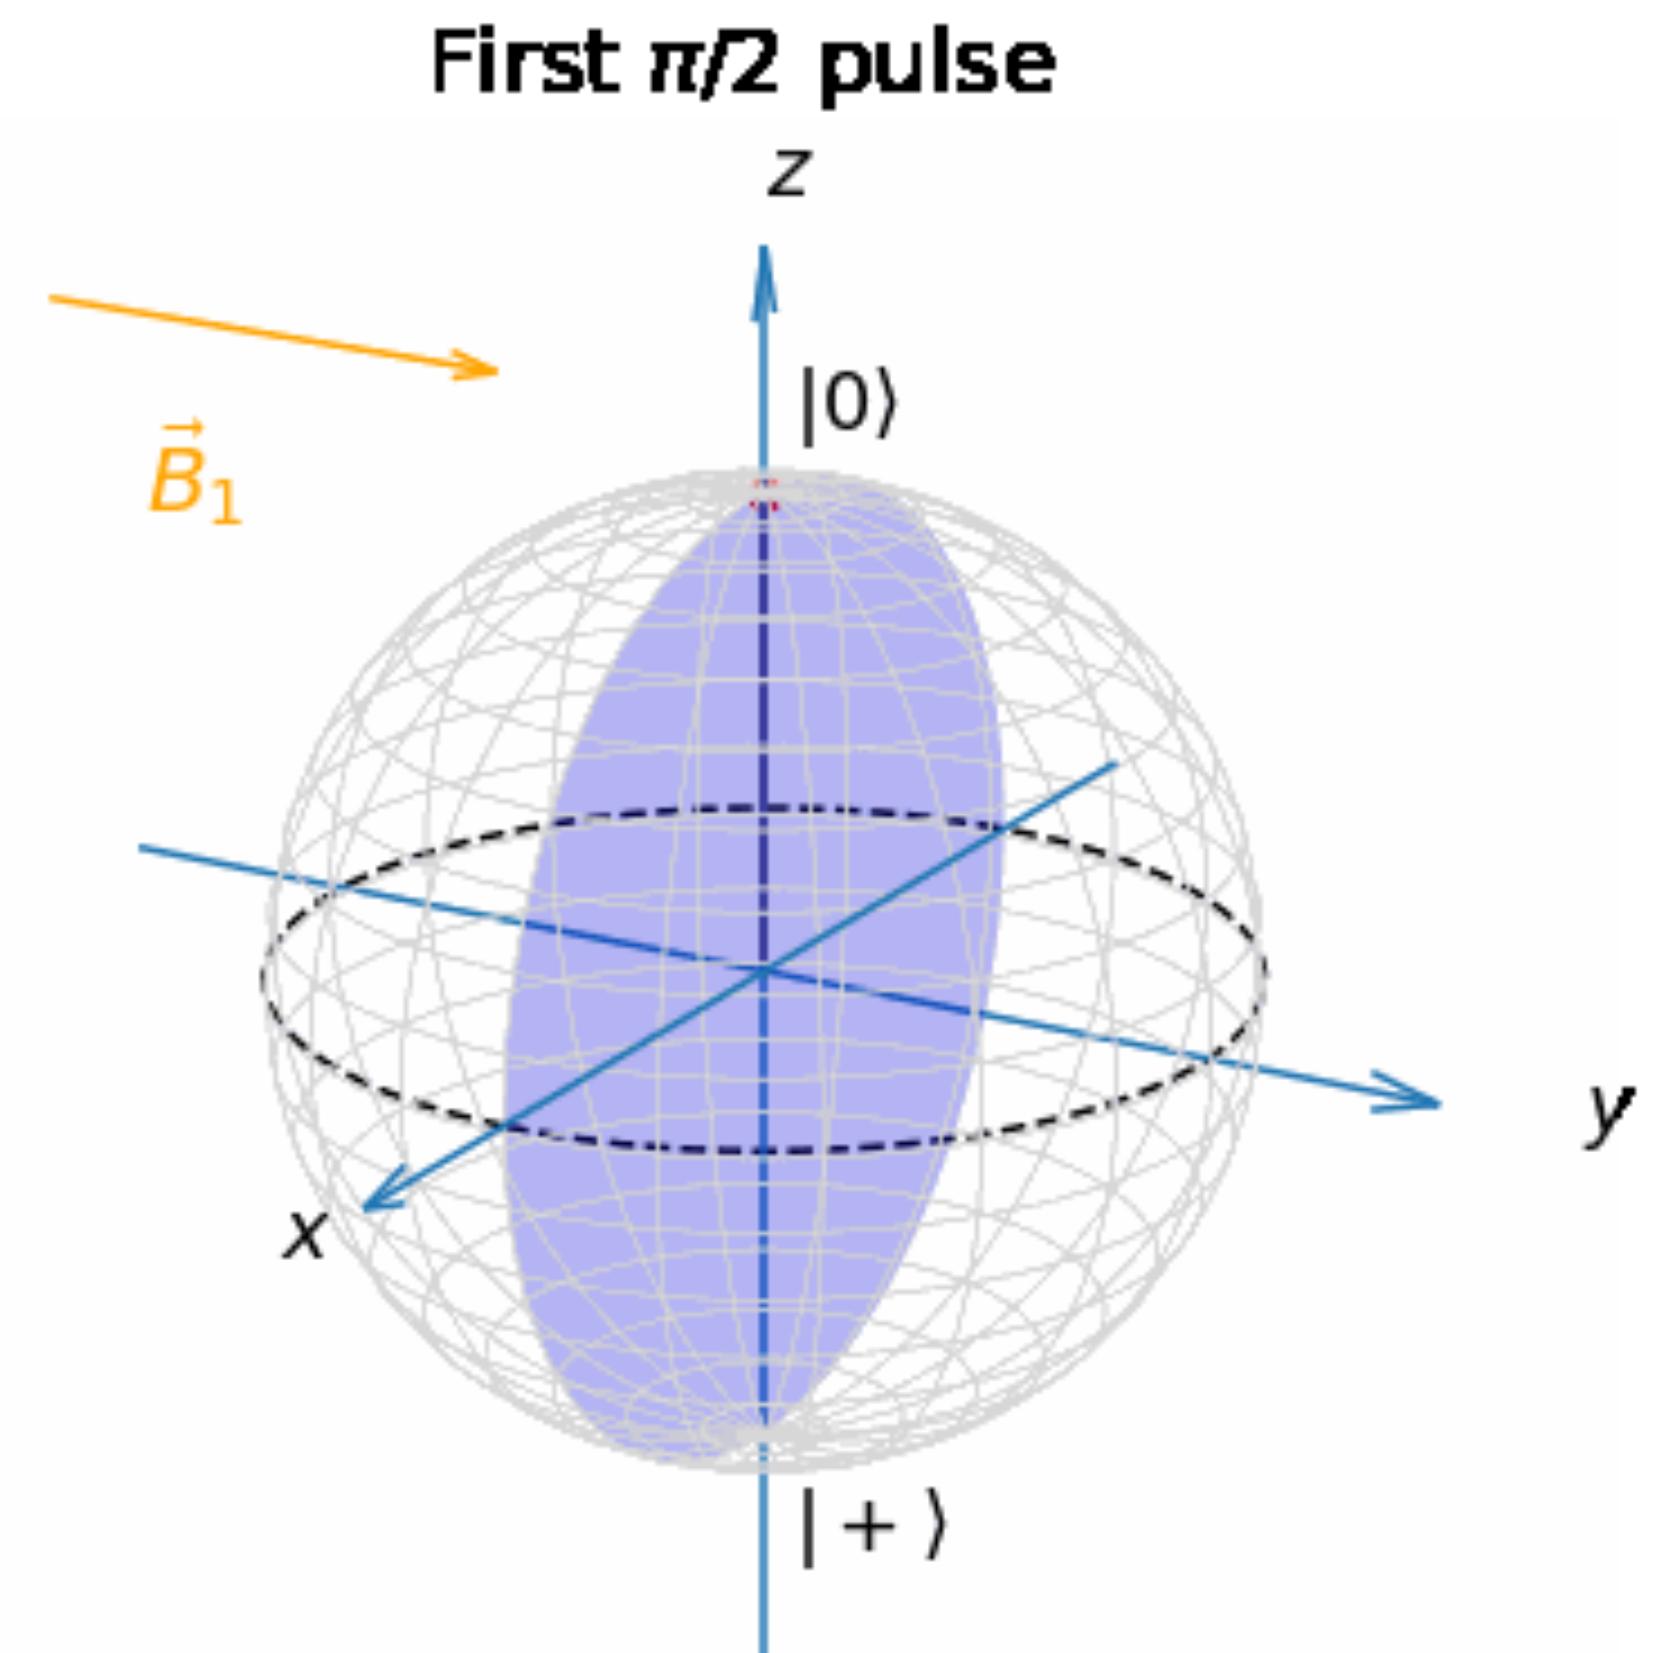

# DM on resonance

If  $m/2\pi \simeq f$ , DM field itself works as a driving field

“Resonance” sequence for  $m/2\pi \simeq f$

1.  $(\pi/2)_y$  pulse
2. Free precession for duration  $\tau \sim T_2^*/2$
3. Fluorescence measurement

$$S \propto B_{\text{DM}}^y \tau$$

# On resonance sensitivity

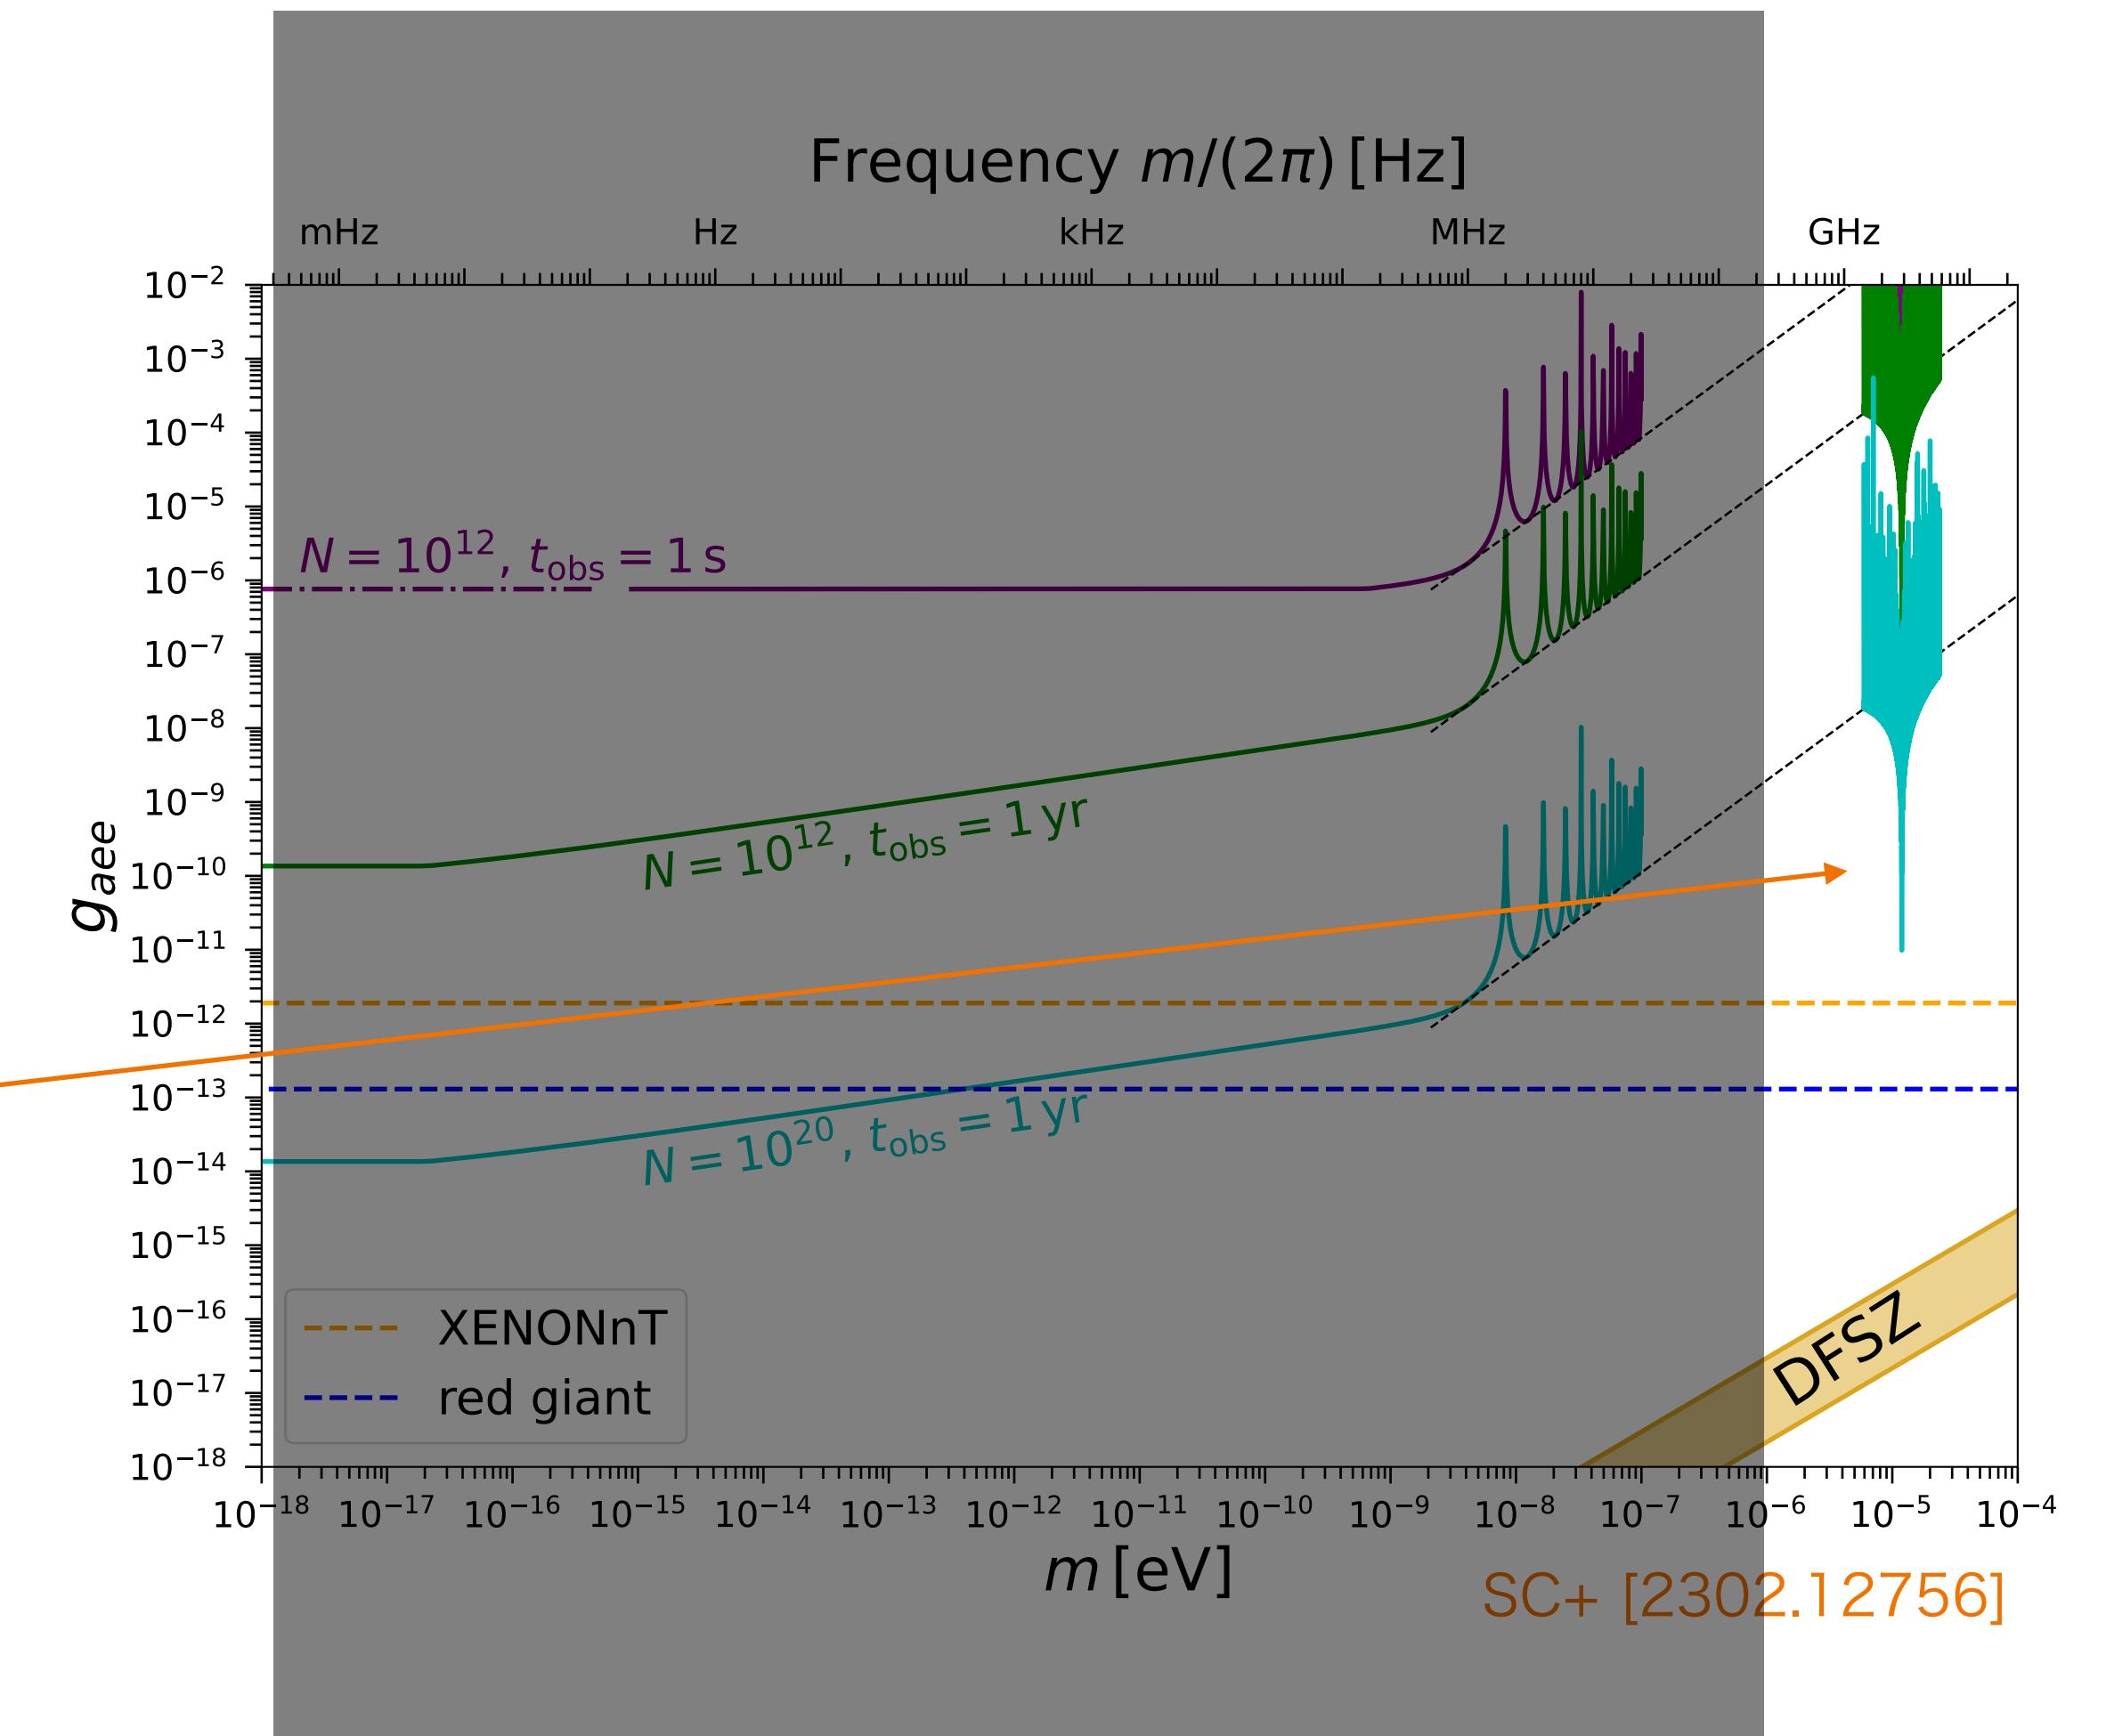

- Resonance position

$$\frac{m}{2\pi} \simeq 2.87 \text{ GHz} \Leftrightarrow m \simeq 11.9 \mu\text{eV}$$

- Tunable with e.g., external magnetic field  $\mathbf{B}$

- Resonant enhancement of sensitivity w/

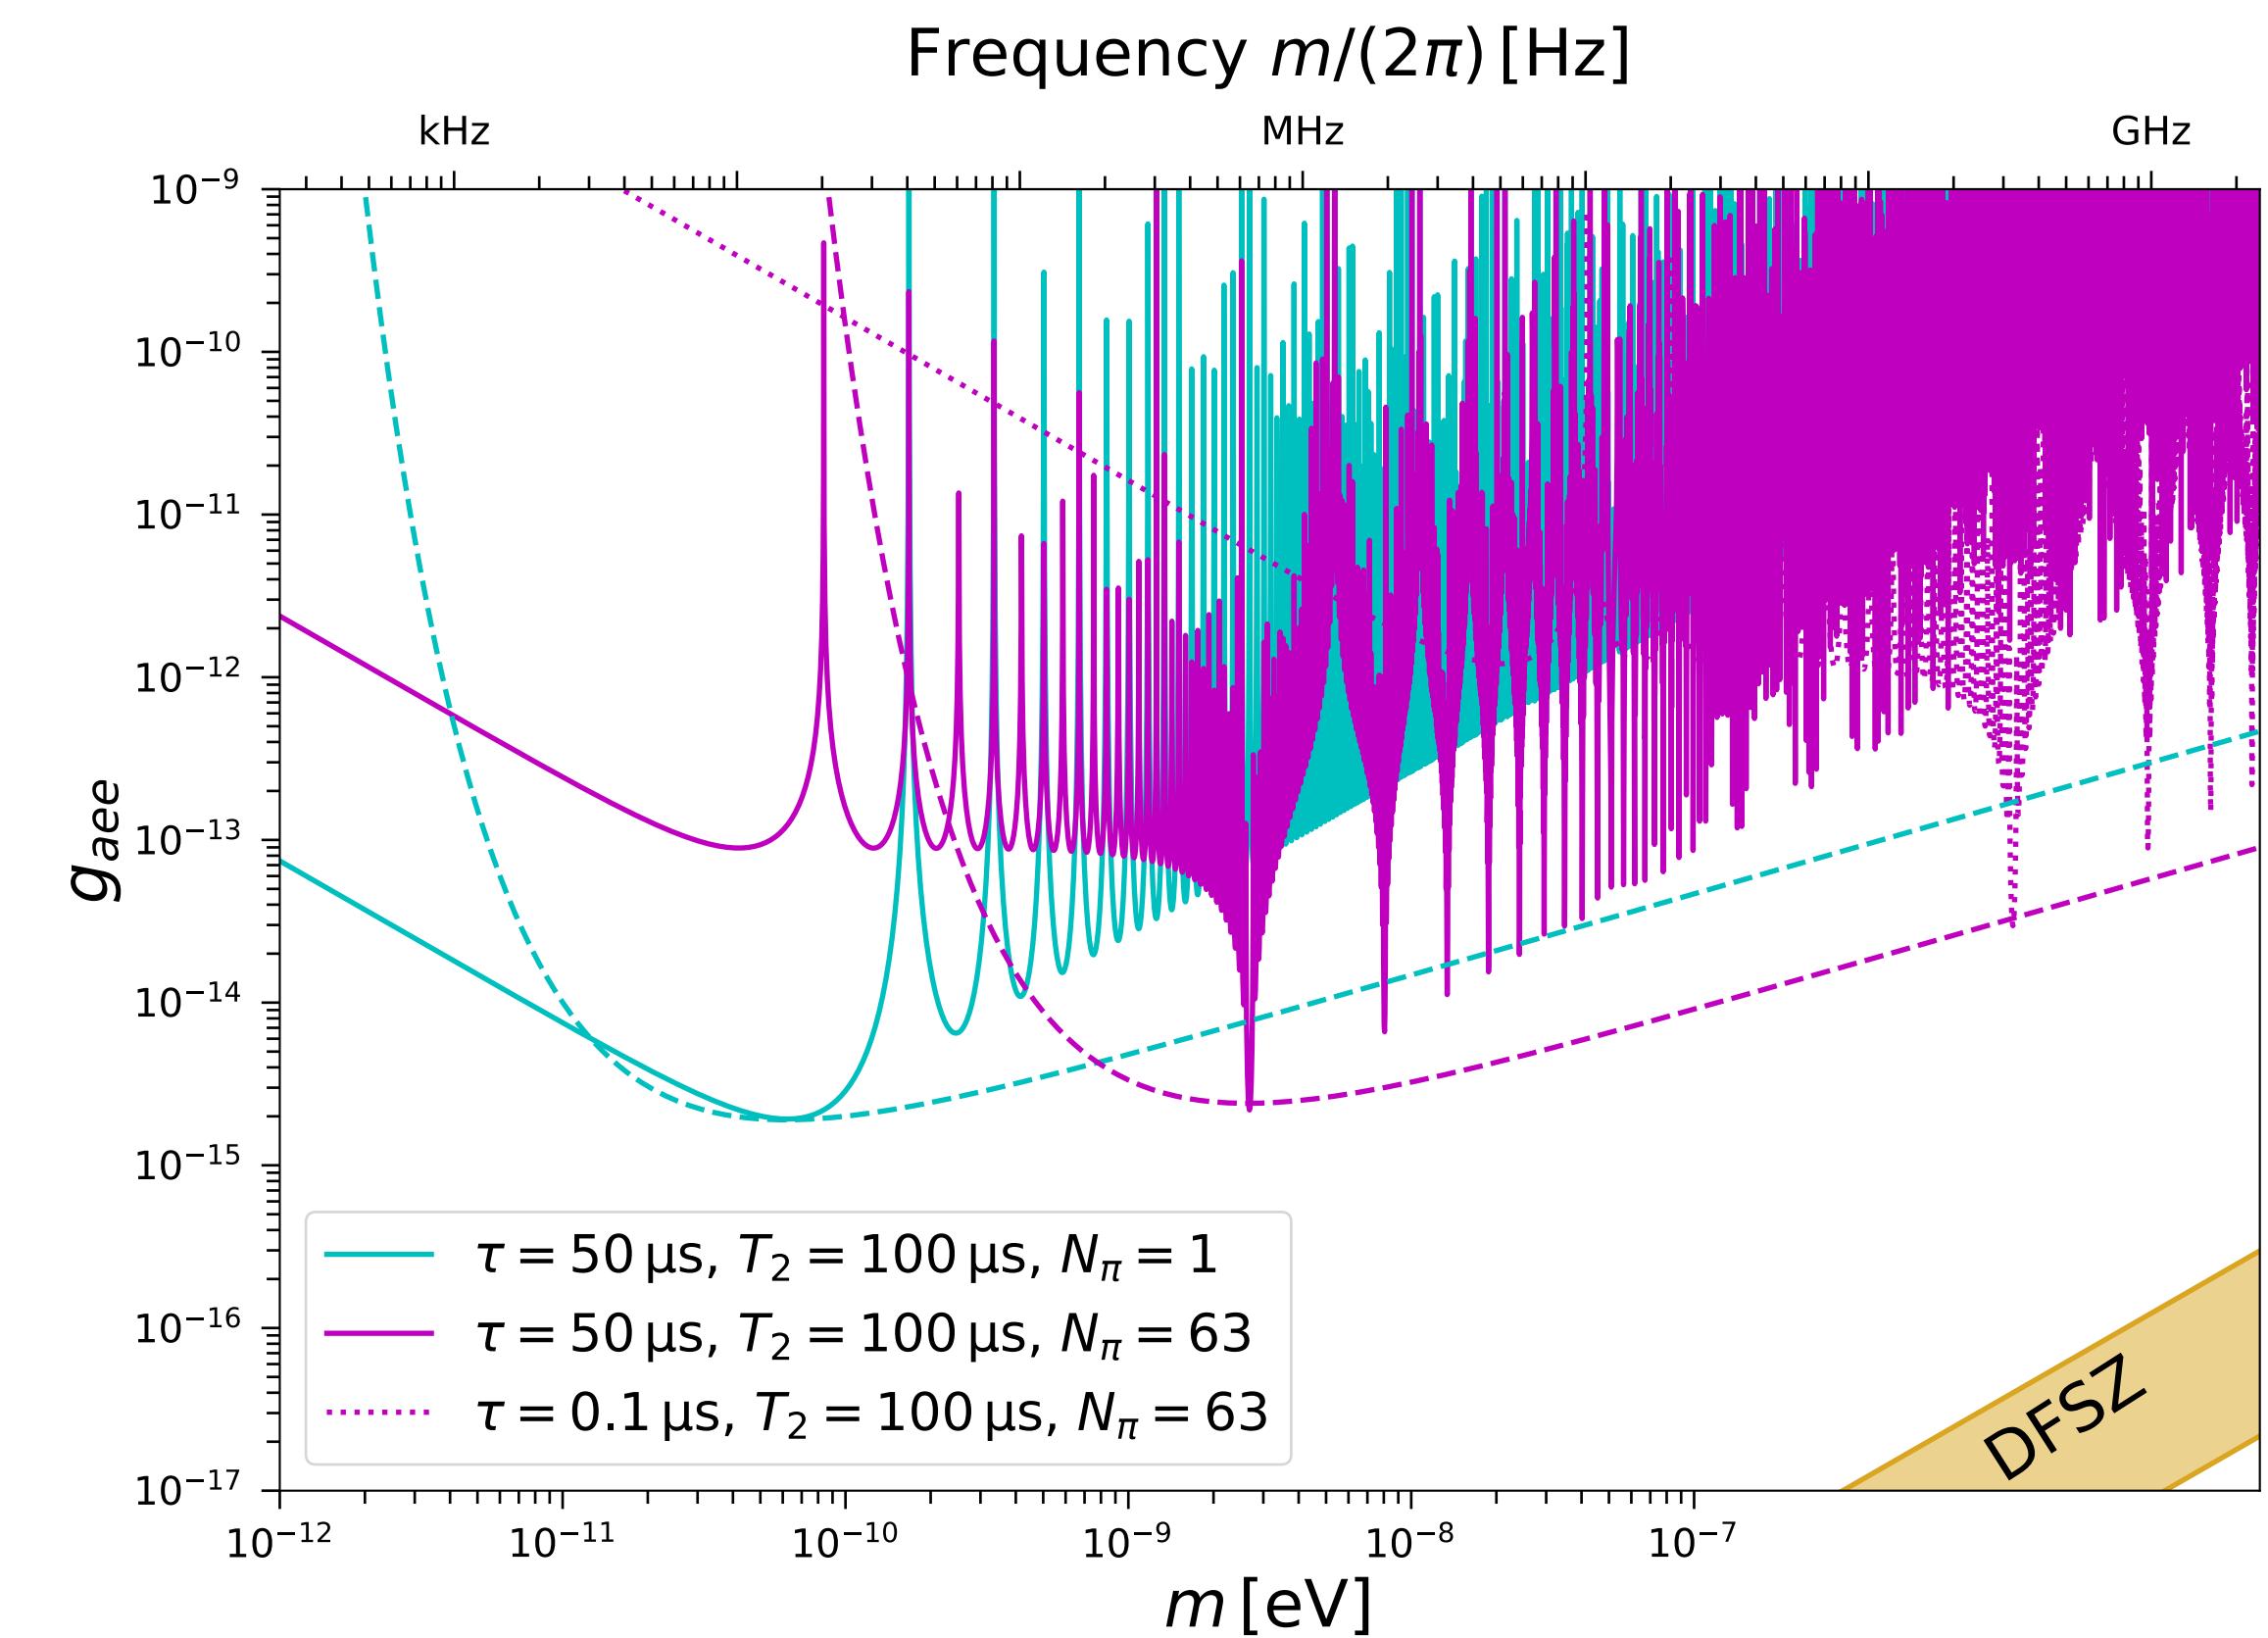

$$m\tau \sim 2 \times 10^4 \left( \frac{\tau}{1 \mu\text{s}} \right)$$

# Towards sensitivity improvement

- ▶ Using More  $\pi_y$  pulses prolongs  $T_2$ 
  - Upper limit on  $T_2 < T_1$
  - target frequency  $\times N_\pi$
- ▶ Lower temperature prolongs  $T_2, T_1$   
( With  $N_\pi = 1023$  )
  - 300 K :  $T_2 = 100 \mu\text{s}, T_1 \sim 1 \text{ ms}$
  - 77 K :  $T_2 = 1 \text{ ms}, T_1 \sim 1 \text{ s}$
  - 4 K :  $T_2 = 10 \text{ ms}, T_1 \gg 1 \text{ s}$
  - 0.1 K :  $T_2 = 0.1 \text{ s}, T_1 \gg 1 \text{ s}$

D. Herbschleb, private communication

# Technical noise mitigation

## II. MAGNETOMETRY METHOD

In many high-sensitivity measurements, technical noise such as  $1/f$  noise is mitigated by moving the sensing bandwidth away from dc via upmodulation. One method, common in NV-diamond magnetometry experiments, applies frequency [12,32,41,42] or phase modulation [19,43–45] to the MWs addressing a spin transition, which causes the magnetic-field information to be encoded in a band around the modulation frequency. Here we demonstrate a multiplexed [46–49] extension of this scheme, where information from multiple NV orientations is encoded in separate frequency bands and measured on a single optical detector. Lock-in demodulation and filtering then extracts the signal associated with each NV orientation, enabling concurrent measurement of all components of a dynamic magnetic field.

J. M. Schloss+ ‘18
