## Non-Fluctuational Signature of the QCD Critical Point

We study the influence of the QCD critical point on the trajectories describing the evolution of the expanding fireball in heavy-ion collisions. We find that the lines of constant specific entropy (entropy per baryon) on the phase diagram are drawn towards a special point on the coexistence (first-order) line where the specific entropy reaches a maximum [1]. We study the interplay between this feature of the isentropic trajectories and the freezeout curve. If the critical point is located near the freezeout curve, a region inaccessible by isentropic expansion appears on the freezeout curve. This behavior of the isentropes could provide a novel, non-fluctuational signature of the critical point requiring significantly lower statistics than the fluctuational signatures.
