Study of Entanglement Enabled Spin Interference in peripheral Au+Au collisions with coherently photoproduced rho mesons in the STAR experiment

Entanglement Enabled Spin Interference (EESI), an example of the Cotler-Wilczek process, was used to measure the structure of nuclei and neutron skins in ultraperipheral (UPC) Au+Au and U+U collisions. Study of the interference in peripheral collisions provides novel information on the impact parameter dependence, the entanglement criteria, and wavefunction decoherence. On one hand, the medium created in such collisions can act as a semi-opaque screen and decohere or weaken the interference effect. On the other hand, the interference is expected to be stronger as the impact parameter decreases. Furthermore, it remains unclear whether the coherence of the photon/pomeron emitters can be preserved, despite the breakup of nuclei in hadronic interactions.

In this poster we will present the p_T and centrality dependence of the $\langle 2\cos(2\Delta\phi) \rangle$ modulation of photoproduced ρ mesons in peripheral Au+Au at $\sqrt{s_{NN}} = 200$ GeV collisions measured with the STAR experiment. The data will be compared to theoretical model calculations. The interpretation of the results will be discussed in the framework of the Cotler-Wilczek process and future opportunities for nuclear physics will be proposed.
