The Problem

- A high mass discovery would therefore likely proceed differently than many discoveries in the past, facing different challenges.
- Experimental uncertainties reduce with time and effort, but difficult to reduce theory uncertainties without further input.

The Problem

- A high mass discovery would therefore likely proceed differently than many discoveries in the past, facing different challenges.
- Experimental uncertainties reduce with time and effort, but difficult to reduce theory uncertainties without further input.

- (Above) PDF eigen-vector variation and PDF choice uncertainty (%)

The Problem

- Resonance Searches: theory uncertainties reduce sensitivity but mainly hamper efforts to distinguish between models.

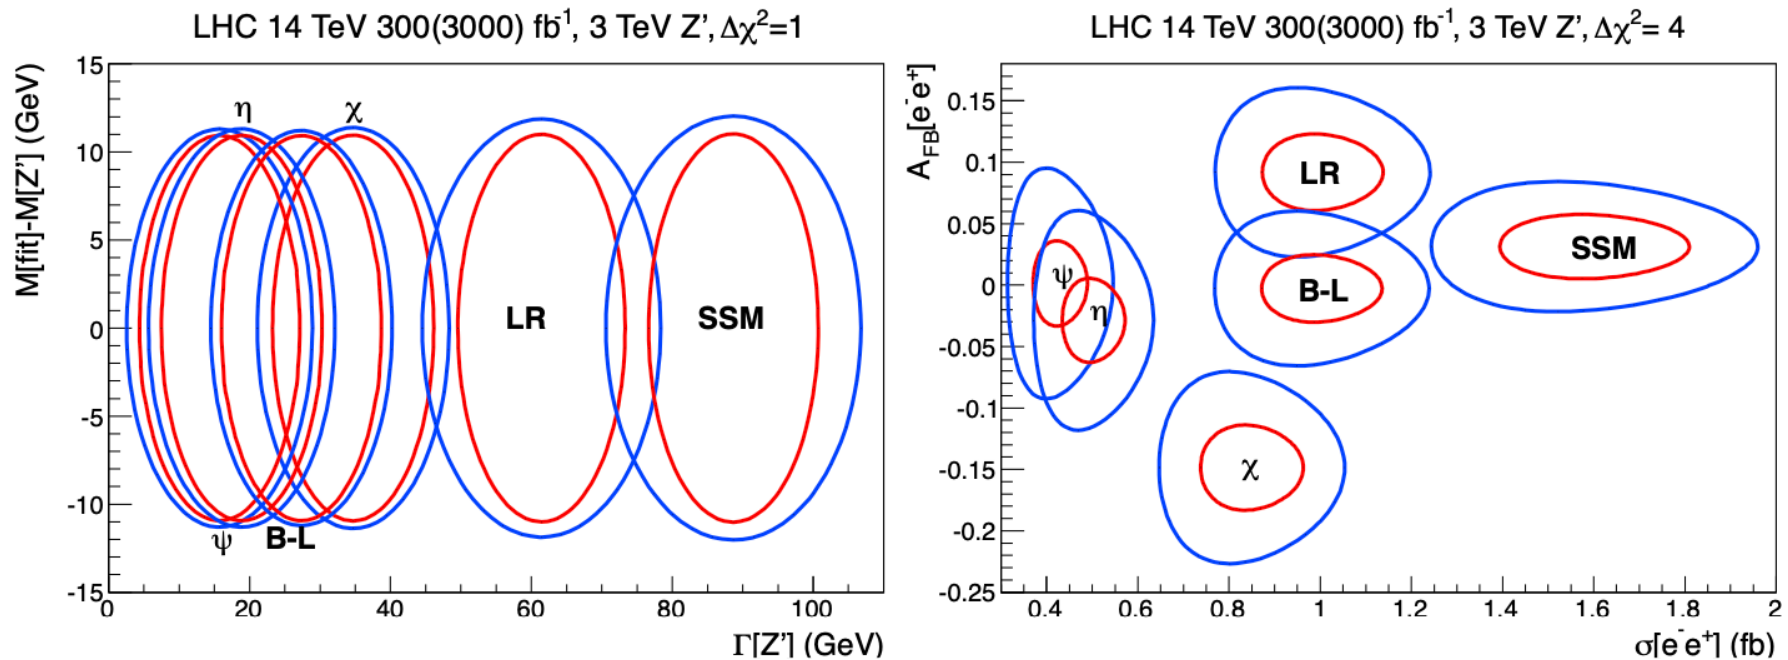

Figure 2. The results for $pp \rightarrow Z' \rightarrow e^-e^+$ with dielectron invariant mass from 2.8 – 3.2 TeV. *Left panel:* $\Delta\chi^2 = 1$ contours for the fitted width versus mass for the LHC at 300 fb⁻¹ and 3000 fb⁻¹. *Right panel:* $\Delta\chi^2 = 4$ contours of the simulated forward-backward asymmetry versus the cross section.

<https://arxiv.org/abs/1308.2738>

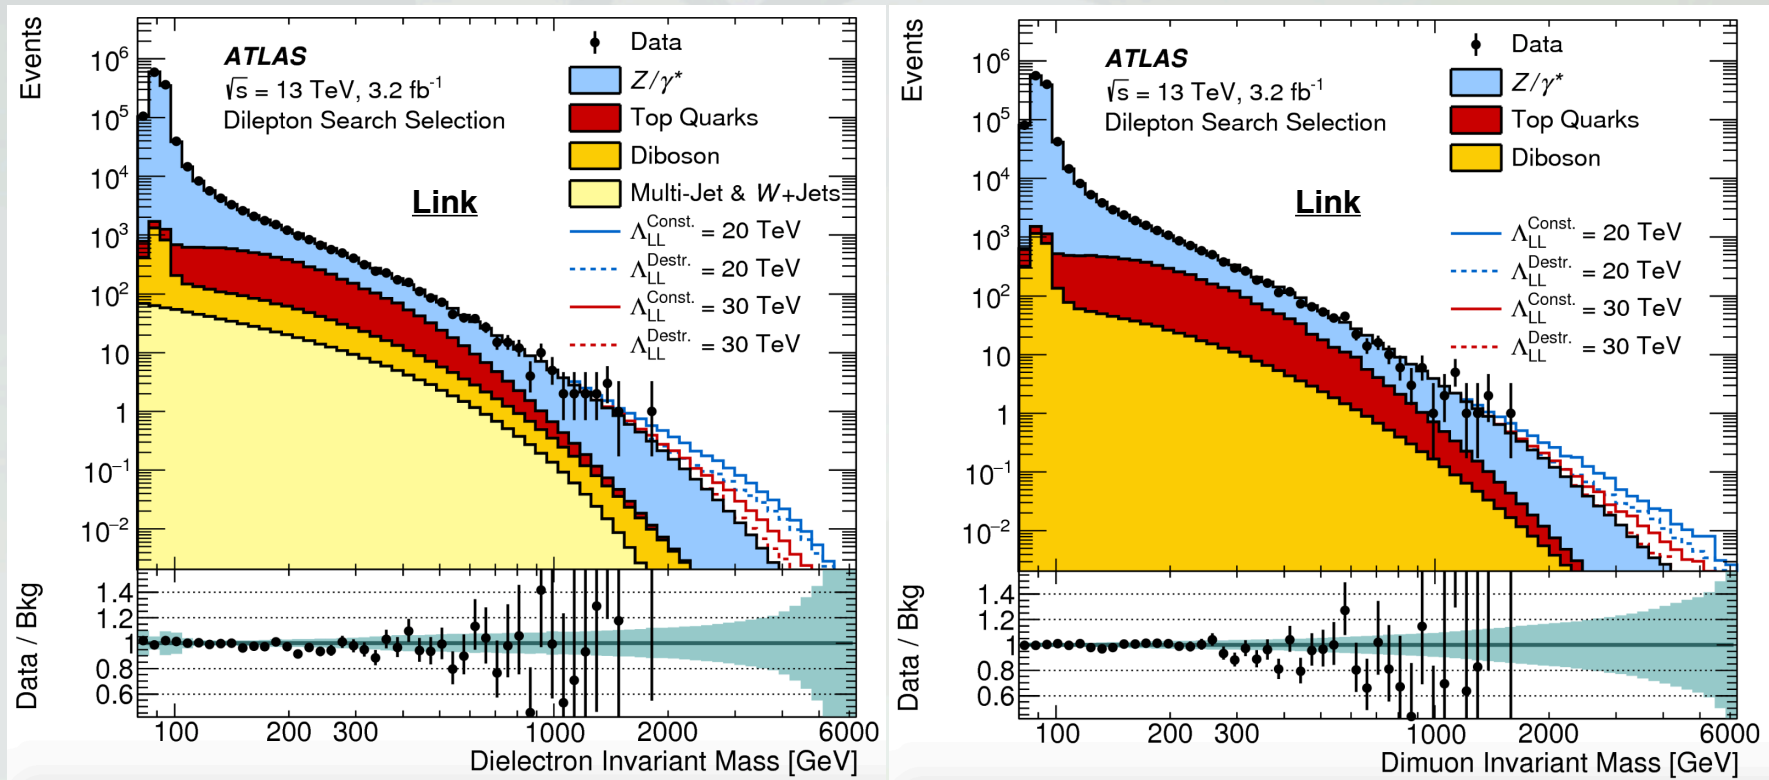

The Problem

- Resonance Searches: theory uncertainties reduce sensitivity but mainly hamper efforts to distinguish between models.
- Non-Resonant searches: The situation becomes dire. The uncertainties are so large that you might completely lose sensitivity.

The Problem

- Resonance Searches: theory uncertainties reduce sensitivity but mainly hamper efforts to distinguish between models.
- Non-Resonant searches: The situation becomes dire. The uncertainties are so large that you might completely lose sensitivity.

ePump to the Rescue

[Link](#)

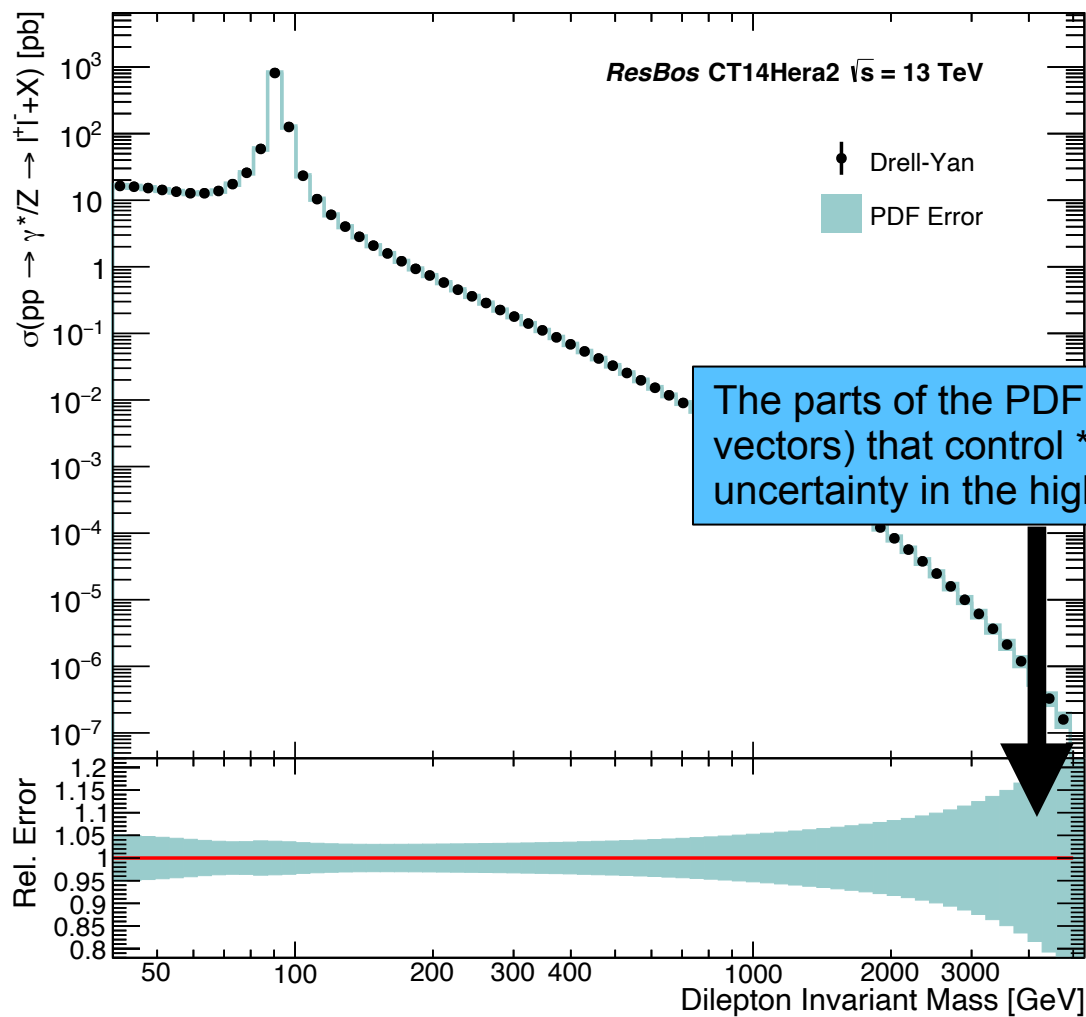

- In 2019 we (Willis, Brock, Hayden, Hou, Isaacson, Schmidt, Yuan), published a paper identifying a way to tackle this issue.

- Re-discovered that the LHC is a very good: up - anti-up quark collider!
- A careful selection of data at low mass (where no signal is expected) could be used to constrain the high-mass PDF uncertainties.

Considering Forward-Backward Asymmetry

[Link](#)

- A recent follow up (Fu, Brock, Hayden, Yuan) looked at using forward-backward asymmetry (AFB) as a discriminating variable.

$$A_{FB} = \frac{N_F - N_B}{N_F + N_B},$$

FIG. 9. Comparison of the A_{FB} (left) and Dilution (right) with different PDF input for MCFM at NLO accuracy in the high mass region ($M_{ll} > 3000$ GeV). The band represents the PDF uncertainty.

<https://arxiv.org/abs/2307.07839>

Considering Forward-Backward Asymmetry

[Link](#)

- In this study looked at using AFB at high mass to see if this could potentially improve PDF uncertainty and help differentiate between PDFs.

FIG. 6. PDF update of CT18 for \bar{u}/u (left), and \bar{d}/d (right) using A_{FB} pseudo-data generated using MSHT20 and NNPDF4.0. The central value and uncertainty are compared to the CT18 central value.

- With 300 or 3000 fb, the PDF uncertainty is not improved by much, but is enough to differentiate between the different modern PDFs.

<https://arxiv.org/abs/2307.07839>

Further Studies

- This was a study using Neutral-Current Drell-Yan, what about Charge-Current?
 - Yao has been working on this too!
 - Triple differential measurements in both NCDY and CCDY look promising.
 - Appears that charge asymmetry also has something to add.
- For the non-resonant searches: at what level of theory uncertainty or integrated luminosity from the LHC do we lose sensitivity completely?
 - Once we establish the above, how much does this theory uncertainty reduction method help? What happens if you push the reduction even further?
