

# ATLAS measurements of Drell Yan processes

#### Mingzhe Xie

#### On behalf of ATLAS collaboration

2024.10.20

#### Drell-Yan process

• Proposed in 1970s, play an important role in both electroweak, PDF and QCD

- Electroweak precision measurement
  - W mass and width at 7TeV
- **QCD and Proton inner structure (PDF)** 
  - <u>W, Z cross sections and their ratio</u> at 13.6 TeV
  - Z+b/c jets cross sections
  - W, Z pT distribution
- New physics search
  - Missing transverse momentum
     +jets cross sections

#### ·

2024/10/15

## W boson mass and width at $\sqrt{S} = 7$ TeV

#### W boson mass

- As a fundamental parameter of standard model (SM), crucial to both validation of standard model and probe for potential new physics.
- Two most precise measurements:
  - CDF: differ from SM prediction around  $7\sigma$
  - CMS: agree well with SM.

#### • W decay width $arGamma^W$

- Comparison between measured value and SM prediction probe for new particles
- Current world average  $2085 \pm 42$  MeV from LEP-2 and Tevatron, **NO** LHC measurements

 $\Delta r$  represents the radiative corrections within SM and the extensions of it.

 $M_W^2 \left( 1 - \frac{M_W^2}{M_Z^2} \right) = \frac{\pi \alpha}{\sqrt{2}G_W} \left( 1 + \Delta r \right)$ 

#### W mass reanalysis using 7 TeV data

Previous result

 $m_W = 80370 \pm 7 \text{ (stat.)} \pm 11(\text{exp. syst.})$ 

•  $\chi^2$  offset method

$$\pm$$
 14 (mod. syst.) MeV

 $= 80370 \pm 19 \,\mathrm{MeV},$ 

- Major updates
  - **Profile likelihood**  $\mathcal{L}(\vec{n}|\mu,\vec{\theta}) = \prod_{i} \prod_{j} \operatorname{Poisson}\left(n_{ji}|\nu_{ji}(\mu,\vec{\theta})\right) \cdot \operatorname{Gauss}\left(\vec{\theta}\right)$ , representing experimental
- Simultaneous fit of mw and nuisance parameters representing experimental and modelling uncertainties

Fitting strategy

	Nuisanse parameters	Fitting Range
$p_T^l$	214	30-50GeV
$m_T$	223	60-100GeV

 $p_T^W$  modelling validated with the latest measurement

- Combined by BLUE method with the correlation estimated from fluctuated toys  $\rho \sim 50.4\% \rightarrow w(p_T^l) \sim 86\%$  (for CT18NNLO)
- Final result dominated by  $p_T^l$  fit

## New W mass result at $\sqrt{S} = 7$ TeV

#### • A dependence on the PDF choice is tested

	CT14	CT18	CT18A	MMHT2014	MSHT20	NNPDF3.1	NNPDF4.0	ATLASpdf21
Central value	80363.6	80366.5	80357.2	80366.2	80359.3	80349.6	80345.6	80367.6
Total unc.	15.9	15.9	15.6	15.8	14.6	15.3	14.9	16.6

#### CT18 is chosen as the baseline

 $m_W = 80366.5 \pm 9.8 \text{ (stat.)} \pm 12.5 \text{ (syst.)} \text{ MeV} = 80366.5 \pm 15.9 \text{ MeV},$ 

Central value decreased by 3 MeV, total uncertainty reduced by 3 MeV (16%)

5

## W width measurement at $\sqrt{S} = 7$ TeV

#### • Same strategy used as $m_W$ measurement

- $\Gamma_W = 2202 \pm 32 \text{ (stat.)} \pm 34 \text{ (syst.) MeV} = 2202 \pm 47 \text{ MeV},$  $w(m_T) \sim 87\% \text{, dominated by } m_T \text{ fit}$
- First measurement at LHC, most precise experimental results at present

Simulaneously determination of  $m_W$  and  $\Gamma_W$ , yield  $m_W = 80354.8 \pm 16.1 \text{ MeV}$  $\Gamma_W = 2198 \pm 49 \text{ MeV},$ 

 $p_T^W$  and  $p_T^Z$  at  $\sqrt{S} = 5.02/13$  TeV

- A sensitive test of QCD
  - higher order corrections
  - non-perturbative effects such as the primordial  $k_T$  of the incoming partons
- $p_T^V \leq 30$  GeV are particularly important for the measurement of W mass
  - can be used to tune QCD model which affects the  $p_T^l$  and  $m_T$  distributions

#### Strategy

- To reduce pile-up, low  $< \mu >$  data was used, 255  $pb^{-1}$  at 5.02 TeV, 338  $pb^{-1}$  at 13 TeV
- Both electron and muon final states used
- $p_T^W$  unfolded from hadronic recoil  $\vec{u}_T$
- $p_T^Z$  measured through the dilepton system  $p_T^{ll}$
- Hadronic recoil calibration
  - $\vec{u}_T = -\vec{p}_T^V$  is valid for both W and Z
  - Well-measured dilepton system can thus be used to calibrate the hadronic recoil response, and the unfolded  $p_T^{ll}$  distribution provides a cross-check of the  $p_T^Z$  spectrum measured from  $u_T$

 $p_T^W$  and  $p_T^Z$  at  $\sqrt{S} = 5.02$  TeV

Data vs various PDF predictions

- DYTURBO generally agrees well with data
- PDF predictions have only small difference

Data vs various MC predictions

- MC predictions tuned to 7 TeV data (Powheg+Pythia8 AZNLO, Pythia8 AZ) agrees well with data in low  $p_T$
- Sherpa2.2.5 matches data best at high  $p_T$
- Powheg+Herwig7 does not perform well

2024/10/15

 $p_T^W$  and  $p_T^Z$  at  $\sqrt{S} = 13$  TeV

Same conclusion as in 5.02 TeV

Nice validation of the AZNLO Pythia8 tune, developed for  $m_W$  determination at 7 TeV —

2024/10/15

u/d

d

- Measured results for  $W^+, W^-, Z$ cross sections and their ratios
- generally in good agreement with SM predictions with different PDF sets.

1.25

11

2024/10/15

- $t\bar{t}/W$  cross section ratio given here for the first time at 13.6 TeV
- Lower than the theory predictions of most PDFs, mainly due to the measured  $t\bar{t}$  cross section at 13.6TeV is lower as shown in <u>PLB 848(2024)138376</u>

- Dependence of cross sections on the center-of-mass energy
- Good agreement with theory prediction

## Z + heavy flavor at $\sqrt{S} = 13$ TeV

- Test of perturbative QCD and heavy-flavor quarks inside proton
- Important background of Higgs boson measurements or search for new physics

#### • Measured observables

Table 1: List of observables used to perform differential cross-section measurements.

Observable	Notation pQCD and MC
$p_{\rm T}$ of the leading <i>b</i> -jet $p_{\rm T}$ of the <i>Z</i> boson	$\begin{bmatrix} p_{T,b}^0 \\ p_T(Z) \end{bmatrix}$ modelling
$\Delta \tilde{R} = \sqrt{(\Delta \phi)^2 + (\Delta y)^2}$ between the <i>Z</i> boson and leading <i>b</i> -jet, where $\Delta \phi$ ( $\Delta y$ ) is the azimuthal angle (rapidity) difference	$\Delta \tilde{R}_{Zb}$ PDF model: 4FS vs 5FS
$p_{\rm T}$ of the leading <i>c</i> -jet $p_{\rm T}$ of the <i>Z</i> boson	$\begin{bmatrix} p_{T,c}^{0} \\ p_{T}(Z) \end{bmatrix}$
Feynman- <i>x</i> variable $x_F = 2 p_z(c) /\sqrt{s}$ [25] Cross-section ratio of $p_T(Z)$ in $ y(Z)  < 1.2$ and $ y(Z)  > 1.2$	$\begin{bmatrix} x_F(c) \\ R(p_T(Z)) \end{bmatrix}$ Intrinsic charm
Invariant mass of the two leading <i>b</i> -jets Azimuthal angle difference between the two leading <i>b</i> -jets	$\left[ \begin{array}{c} m_{bb} \ \Delta \phi_{bb} \end{array}  ight] \cdot g  ightarrow b \overline{b} \ {\sf modelling}$
	Observable $p_{\rm T}$ of the leading $b$ -jet $p_{\rm T}$ of the Z boson $\Delta \tilde{R} = \sqrt{(\Delta \phi)^2 + (\Delta y)^2}$ between the Z boson and leading $b$ -jet,where $\Delta \phi (\Delta y)$ is the azimuthal angle (rapidity) difference $p_{\rm T}$ of the leading $c$ -jet $p_{\rm T}$ of the Z bosonFeynman- $x$ variable $x_F = 2 p_z(c) /\sqrt{s}$ [25]Cross-section ratio of $p_{\rm T}(Z)$ in $ y(Z)  < 1.2$ and $ y(Z)  > 1.2$ Invariant mass of the two leading $b$ -jetsAzimuthal angle difference between the two leading $b$ -jets

## Z + heavy flavor at $\sqrt{S} = 13$ TeV

#### **Measurement strategy**

- Background estimation
  - Z+jets background: A likelihood fit on a flavor-sensitive observable ("flavor-fit") to decide the shape and normalization of Z+b-jets, Z+c-jets and Z+light jets, done separately in >=1 flavor-tagged jet and >=2 flavor-tagged jets
  - $t\bar{t}$  and MJ estimated vis data-driven method
  - Other non-Z+jets background estimated via MC simulations
- Bayesian unfolding
- Uncertainty estimation: for each systematic source, repeat the flavor fit, then unfold

## Z + heavy flavor at $\sqrt{S} = 13$ TeV

#### 5FS: massless b-quark **Inclusive cross-sections in the fiducial phase space** 4FS: b quark generated by $g \rightarrow bb$ 3FS: c quark generated by $g \rightarrow c\bar{c}$ ATLAS √s = 13 TeV, 140 fb<sup>-1</sup> ATLAS ATLAS √s = 13 TeV, 140 fb<sup>-1</sup> $Z(\rightarrow II) + \ge 1 \text{ c-jet}$ √s = 13 TeV, 140 fb<sup>-1</sup> $Z(\rightarrow II) + \ge 2 \text{ b-jets}$ $Z(\rightarrow II) + \ge 1 \text{ b-jet}$ -- 20.89 ± 0.07 ± 2.77 pb --- 10.49 ± 0.02 ± 0.59 pb --- 1.394 ± 0.006 ± 0.131 pb Data (stat.)  $\sigma(Z + \ge 2 \text{ b-jets}) \text{ [pb]}$ 

10

15

20

25

- 5FS predict the inclusive cross-sections for both Z+>=1b-jet and Z+>=2b-jets well
- 4FS only works for Z+>=2 b-jets

 $\sigma(Z + \ge 1 \text{ b-jet}) \text{ [pb]}$ 

3FS underestimate the measurement by about  $3\sigma$ , due to lack of resummation of  $\ln(Q^2/m_c^2)$  in the collinear PDF evolution.

30

50

40 45  $\sigma(Z + \ge 1 \text{ c-jets})$  [pb]

## Z + b-jet at $\sqrt{S} = 13$ TeV

## Z + c-jet at $\sqrt{S} = 13$ TeV

#### Investigate the hypothesis of intrinsic charm

- Comparison with various IC models show no ٠ strong evidence for intrinsic charm component in proton.
- Can be used as new inputs to the future QCD ٠ global analysis.

No-IC

models

2024/10/15

## $p_T^{miss}$ plus jets cross sections at $\sqrt{S} = 13$ TeV

- Precise measurement of standard model (SM)
- search and constraint beyond the SM (BSM) physics
- Signal region:  $p_T^{miss}$  + jets  $p_T^{miss} = p_T^{recoil}$
- Control regions: lepton/photon + jets
- $R_{miss} = \sigma(\text{Signal region}) / \sigma(\text{Control region})$ , uncertainties cancels out in the ratio
  - Two different jet topologies, enhance the sensitivity to BSM physics
  - $\geq 1 \text{ jet } (p_T^{jet} > 120 \text{ GeV})$
  - VBF region ( $|\Delta y_{jj}| > 1, m_{jj} > 200 \text{ GeV}$ )

Three BSM-sensitive observables

Jet

- Transverse momentum of hadronic system  $P_T^{recoil}$
- Invariant dijet mass m<sub>jj</sub>
- Jet angular separation  $\Delta \phi_{ii}$
- Unfolding: corrected for detector effects and fiducial phase space
- designed for reinterpretation, no need to repeat detector-simulations

 $\vec{p}_{\mathrm{T}}^{\mathrm{recoil}}$ 

2024/10/15

## $p_T^{miss}$ plus jets cross sections at $\sqrt{S} = 13$ TeV

Differential cross sections compared to state-of-art SM predictions

Good agreement except for the  $m_{jj}$  distribution.

## $p_T^{miss}$ plus jets cross sections at $\sqrt{S} = 13$ TeV

- Discrepancy in modelling and some systematic uncertainties cancels in the ratio  $R_{miss}$
- Better agreement than cross-sections, especially in  $m_{ii}$

21

#### miss plus jets cross sections at $\sqrt{S} = 13$ TeV

#### Implications for physics beyond the Standard Model

Limits from the particle-level  $R_{miss}^{-1}$ • measurements are competitive to that from detector-level ATLAS monojets search

Also similar sensitivity on 2HDM+a model to the  $p_T^{miss}$ -based direct search

800

Particle-level measurements provides as good sensitivity to BSM physics as detector-level searches, amenable to reinterpretation in terms of different models. 2024/10/15 22

#### Conclusions

- Measurement of Drell-Yan process provide important test on several aspects
  - Electroweak
    - W mass and width measurement by reanalysis of 7 TeV data
    - Consistent with the SM fit result
  - QCD
    - W and Z transverse momentum at 5.02 TeV and 13 TeV
    - Especially important for future W mass measurement
  - Proton structure
    - W, Z cross section at 13.6 TeV
    - Z+b/c jets at 13 TeV
    - Provide constraint on both light quark and heavy quark inside proton
  - BSM constraints
    - Missing transverse momentum + jets at 13 TeV
    - Prove the particle-level measurement show same sensitivity to BSM physics
