GridPix Momentum Coverage & EIC Kinematics

At the lowest momenta particle identification by dE/dx is advantageous.

Promising technology for EIC detector 2

15 GeV on 250 GeV

Electron	Negative Pion
Photon	Negative Kaon
Negative Hadrons	Antiproton

How GridPix is different from Conventional TPC?

1. Truncated mean

- Split the ionization trail into many small samples along the length.
- Reject all measurements whose yield is a factor f higher than the mean of the others.
- Average the remaining samples.

2. Distribution Fit

- Split the ionization trail into many small samples along the length.
- Fit the probability distribution of all the samples to a Landau curve.
- Use the most probable value from the fitted Landau function as dE/dx

Divide the tail as much as possible -> Easy with GridPix

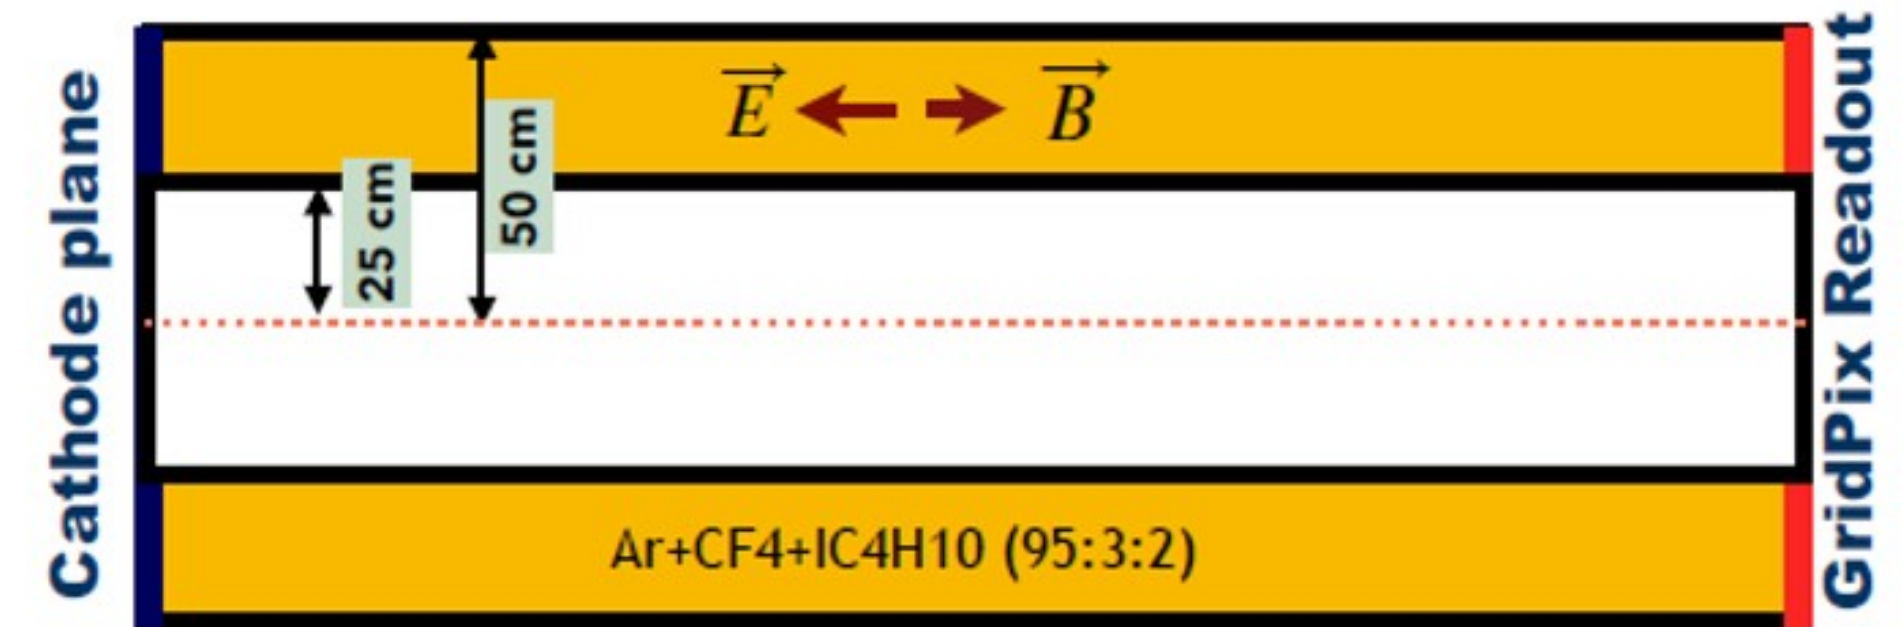

Figure 5: A magnified image of the GridPIX shows the basic operating principle of the chip. An avalanche mesh, similar conceptually to a μ MEGAS, amplifies the electron signal across a small gap. Charge is then collected onto $55 \times 55 \mu\text{m}^2$ silicon pixels.

Few Words about GridPix

Known and Proven Technology for GridPix

- GridPix is a $55\ \mu\text{m} \times 55\ \mu\text{m}$ pixel readout for a gaseous TPC
- First Timepix3 based GridPix test beam (2017)
- Quad module performance from test beam (2018)
- Investigations of the 8 quad detector (2020)

Ultimate dE/dx Device

- Avalanche grid in front of $55 \times 55\ \mu\text{m}^2$ pixels.
- Greater than 90% efficiency for single electrons.

Goal:

- Enough diffusion to get every electron into a different hole
- Count electrons one-by-one.
- Three generations of development and continuing.
- Large area is VERY expensive, but this proposal is small area.

Some References:

- Talk on GridPix for future experiments in Topical workshop on New Horizons in Time Projection Chambers,
- Talk on Timepix4 detectors by X. Llopart in 2nd MUnE Collaboration Meeting at CERN
- PhD thesis on The Pixel-TPC: A feasibility study, by Michael Lupberger

4-sided buttable pixel arrangement

- Model 4 replaces wires bond with bump bond (improves active area) (93.7% \rightarrow 99.5% active area)
- DAQ interface by Through-Silicon-Vias (TSV).

We are in close contact with Jochen Kaminski et. al. from Bonn and having weekly meeting

Anticipated Performance for PID:

● Fit by *Lehraus 1983*:
 $dE/dx \text{ res.} = 5.7 * L^{-0.37} (\%)$

● Fit in **2021** (25 large detectors):
 $dE/dx \text{ res.} = 5.4 * L^{-0.37} (\%)$

Lehraus Plot

- Using 5.4 as a standard TPC
 - $5.4 * (0.25)^{-0.37} = 9.0$
- Measured for GridPIX (truncated Mean)
 - 4.1% at 1 meter
 - $4.1 * (0.25)^{-0.37} = 6.85$
 - This was the prior assumption quoted by us.
- Roughly 20 sigma at 0.5 GeV/c
- Useful range overlaps with DIRC

Overly Simplified Momentum Resolution

- Figure of Merit:

- $$\sigma_p \propto \frac{\sigma_{hit}}{\sqrt{N_{meas}}} \equiv \text{Figure of Merit}$$

- Can be compared to Silicon with detailed Monte Carlo

- Here is simple-minded estimate

- $$\text{Figure of Merit(Si)} = \frac{20 \mu m}{\frac{\sqrt{12}}{\sqrt{4}}} = 2.9 \mu m$$

- Gas:

- Including efficiency ~3000 electrons (minimum!) per track

- Each suffers digitization ($\sigma = 55 \mu m / \sqrt{12} = 16 \mu m$)

- $$\text{Diffusion(Length)} = 25 \frac{\mu m}{\sqrt{cm}} \sqrt{L}$$

- $$D(2cm) = 35 \mu m \rightarrow \text{FOM} = 0.70 \mu m$$

- $$D(25cm) = 125 \mu m \rightarrow \text{FOM} = 2.3 \mu m$$

- $$D(50cm) = 176 \mu m \rightarrow \text{FOM} = 3.2 \mu m$$

- $$D(100cm) = 250 \mu m \rightarrow \text{FOM} = 4.6 \mu m$$

- Although ignoring many significant effects, initial result is on the order of the layers of silicon.

Event Topology and Synchrotron Radiation:

June 2021

Event Pictures at B = 0.5 T

Tracks at
Drift $d = 0.5-1.5$ cm
T2K gas
 $B = 0.5$ T
 $p = 6$ GeV/c

Overview:

- Segmentation: $\frac{55 \mu m}{25 cm} = 4500$
 - 70% active area \rightarrow 3150 “rows”
- 2400 primaries in 25 cm for a MIP.
 - Thousands of hits per track.
- Extremely robust patterns.

Particle Identification via velocity measurement

(Velocity dependent interaction with the detector via. specific ionization)

Traditional charge counting vs cluster counting

Figure 5: Separation power for charge counting, with energy resolution of 4.5% and track lengths of 120 cm and 200 samples along the track.

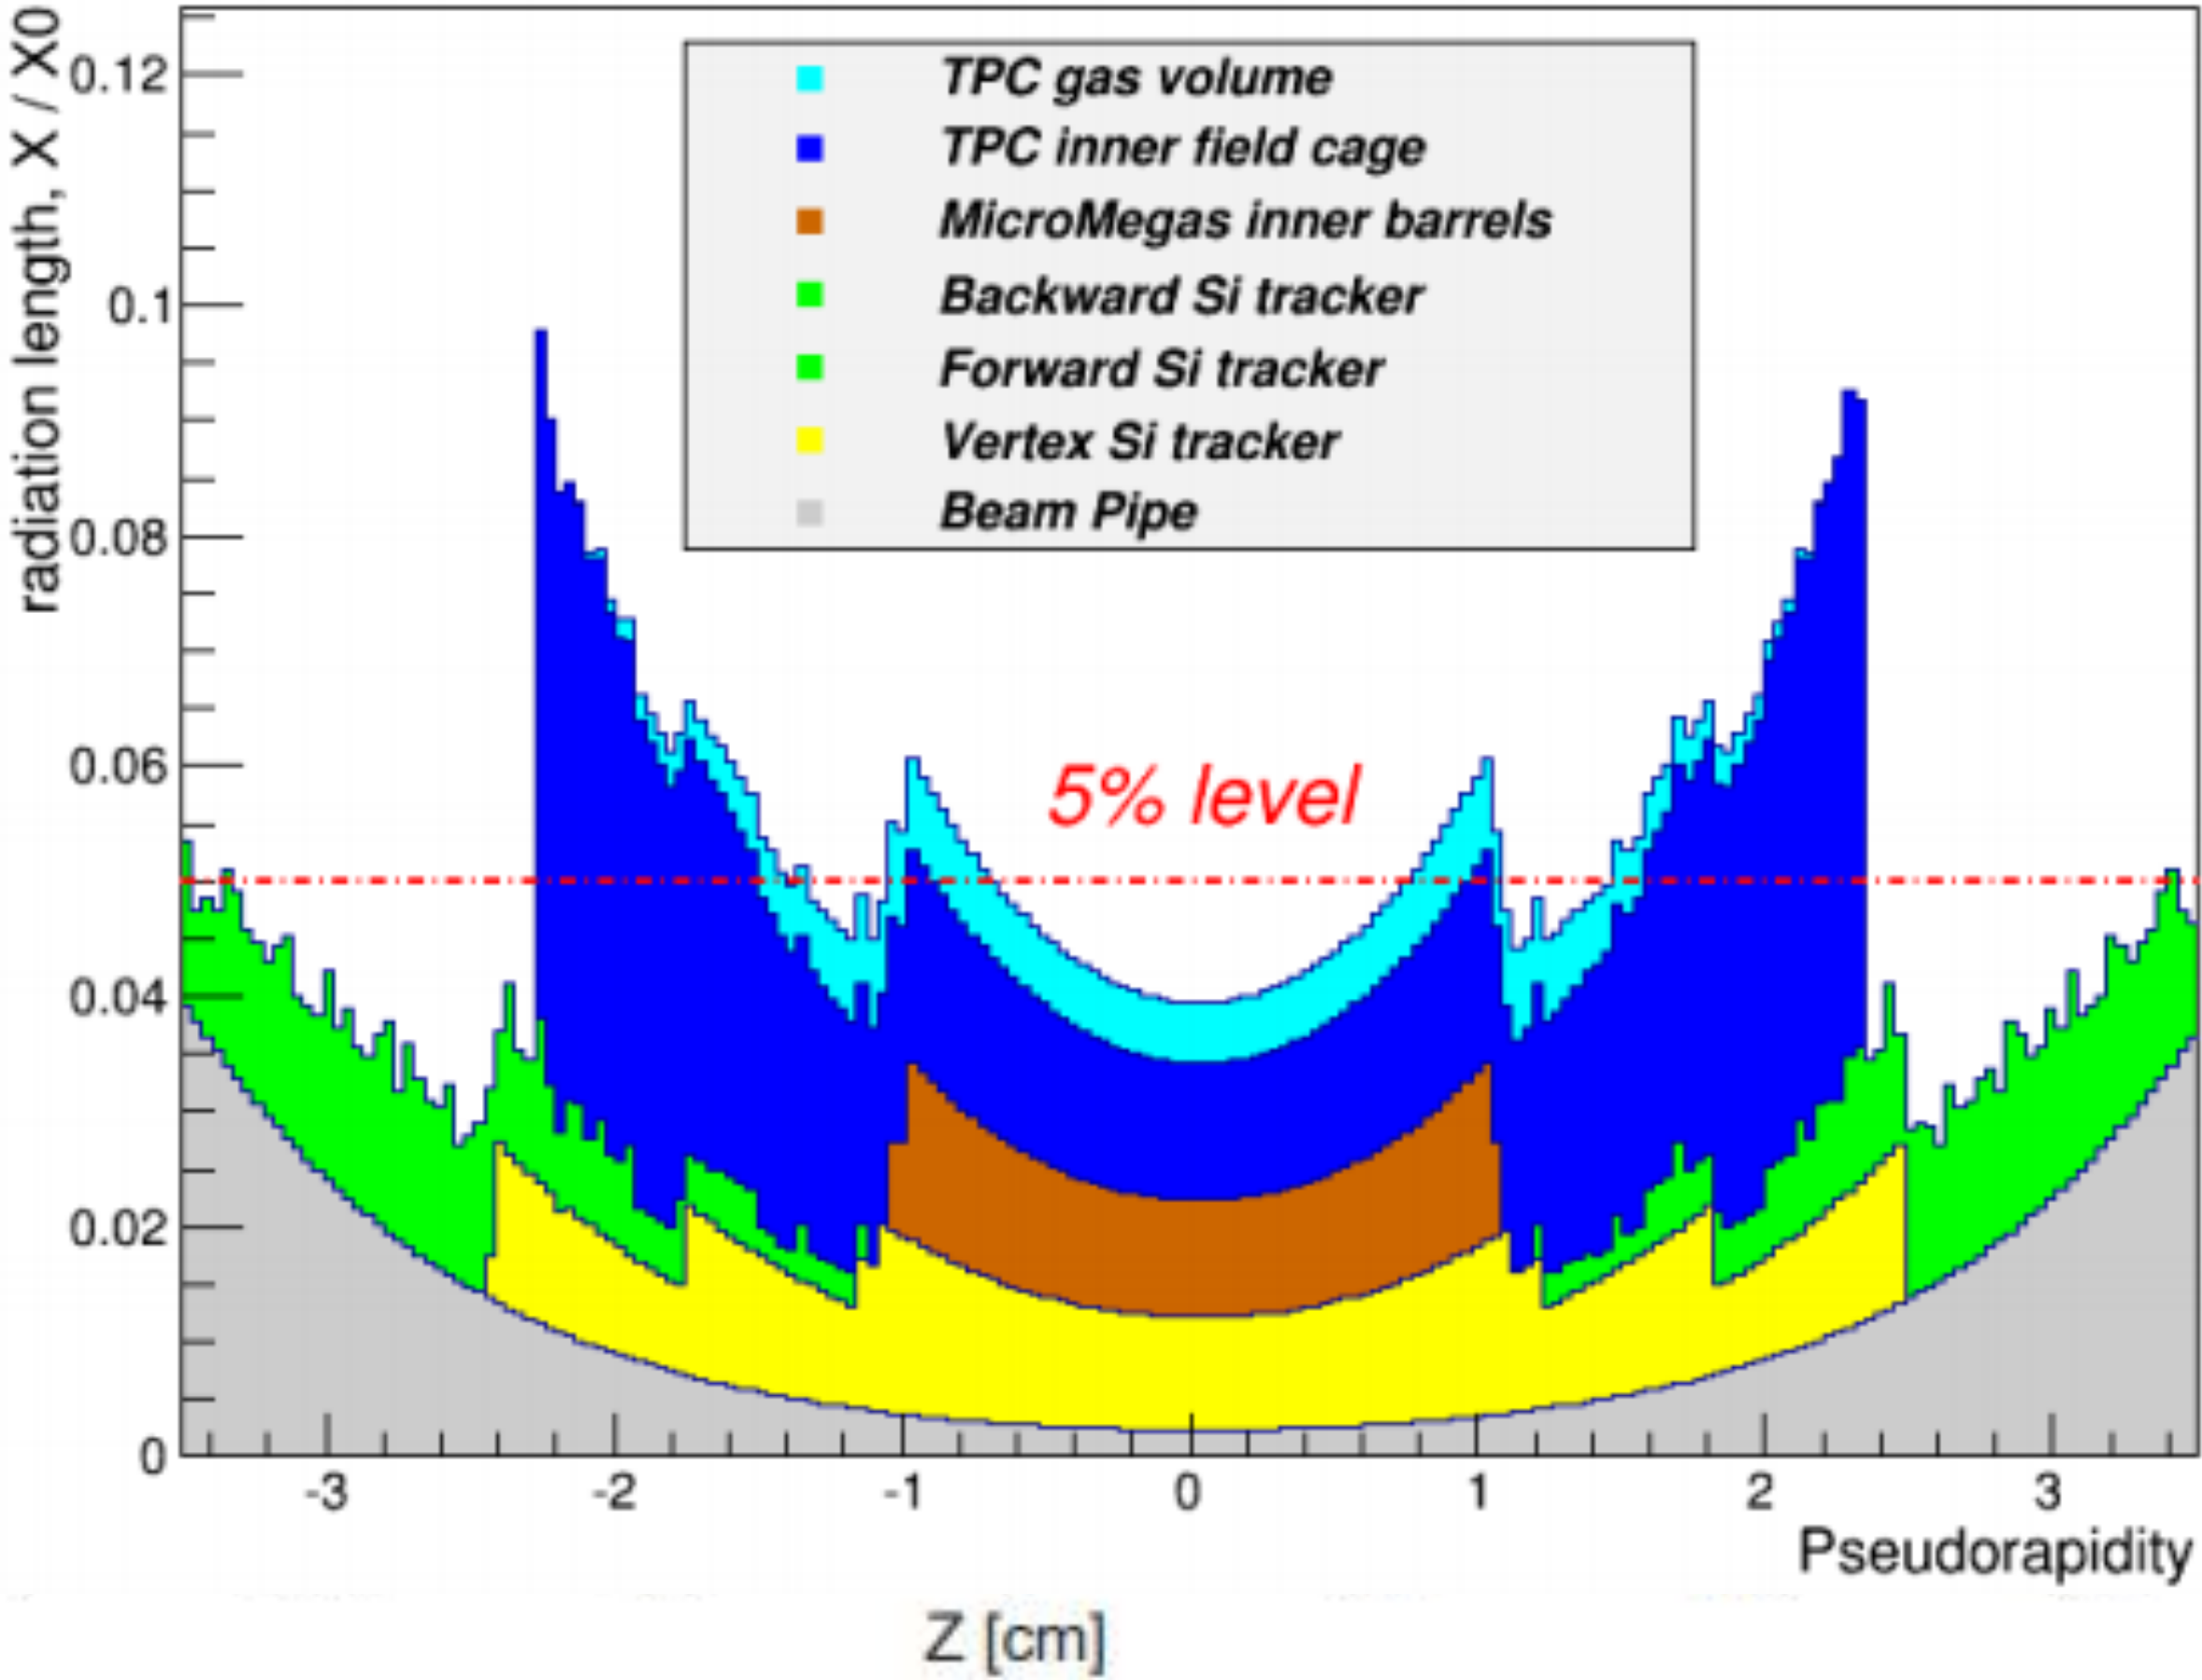

Figure 6: Separation power for cluster counting, for the same gas and track length as in Figure 5. A 100% counting efficiency is assumed.

Typical Radiation Length Scan

EIC Detector Geometry: Radiation Length Scan

STAR TPC as an example:

Large Space & Material Budget of end cap makes TPC less attractive e.g. for EIC

Smaller Space, single ended readout & less Material Budget of end cap can make GridPix more attractive for EIC

Figure 7: $\frac{dE}{dx}$ measured in the STAR TPC. The figure illustrates that the although $\frac{dE}{dx}$ measurements can be challenging in the region of the relativistic rise, the low momentum regime is comparatively simpler.

Motivation to CO2 cooling

- Careful: 1.2 - 5.4 kW of power (occupancy dependent)
- Conventional water cooling is bulky
- Water cooling is not uniform (Important for single electron counting)

- ➔ In general it would be of interest for other detector systems at EIC
- ➔ Plan is to build a portable CO2 cooling system which can be used by others

Pros:

- Known/Proven Technology
- Active further development (Bonn)
- Best $\frac{dE}{dx}$ possible (~count each electron)
- Affordable for a small area
- High resolution tracking
- Low mass in electron arm
- Continuous (aka streaming) readout

Cons:

- ~3 kW of power:
- Must find a low mass way to handle.
- Services “bulky” (compared to just Si)
 - Gas
 - HV membrane
 - Cooling
 - DC power lines (3kV goes in too)

The TPC with two phase CO2 cooling

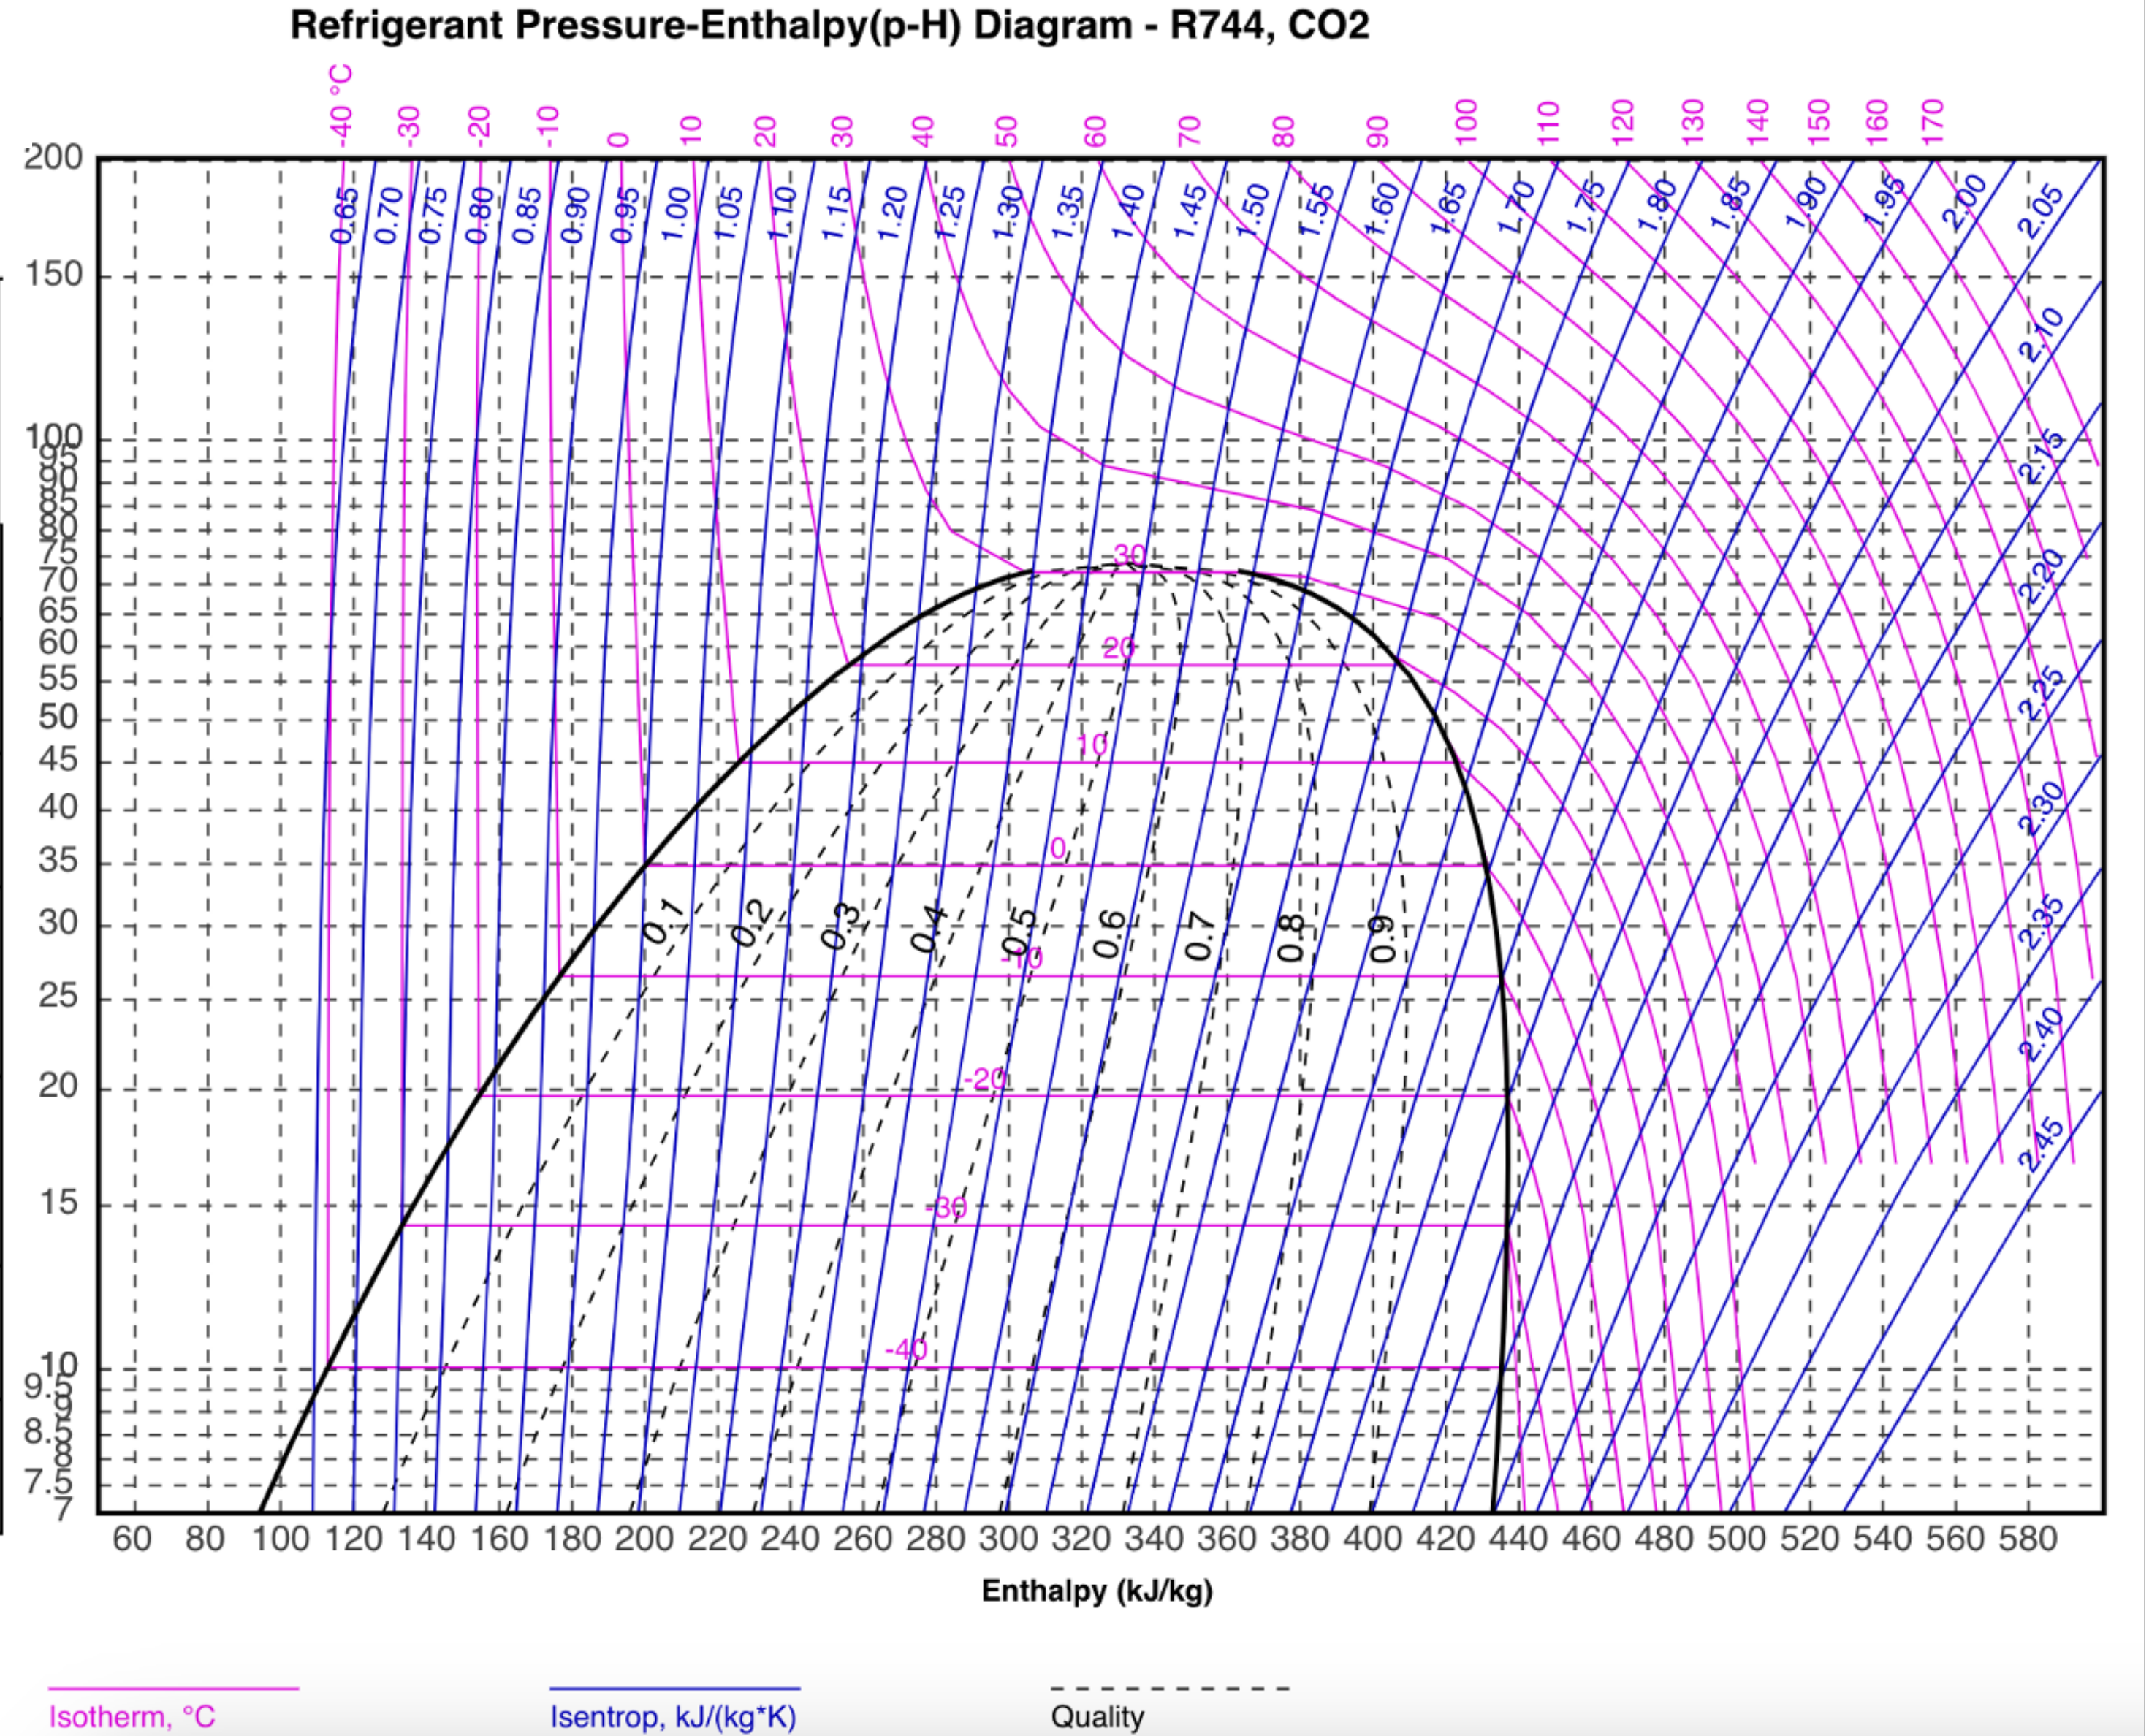

The thermo-physical properties of CO2 make it an attractive gas for cooling in particle detectors:

- CO2 has a high volumetric cooling capacity, because of its large latent heat.
- Does not require a high flow rate or corresponding tubing
- Low viscosity facilitating a uniform flow
- Non-toxic
- Radiation hard
- The pressure controls the evaporation temperature, and at 65 bar it can take out heat at room temperature.
- A CO2 cooling system is expected to be able to extract the generated ~kW of heat per end plate.

P-H Chart

Point on graph	Description	Pressure (bar)	Temperature (°C)
1	CO ₂ bottle	59	20
2	Entry to HX annulus	55	18.3
3	Exit from HX annulus	55	15.4
4	Entry to Environment chamber	50.9	15
5	Exit from Environment chamber	50.9	15
5a	Entry to HX shell	50.9	15
6	Exit from HX shell	50.9	15

Summary

- ◎ Large Material budget -> A significantly reduced material budget with GridPIX
- ◎ Large Volume -> Relatively smaller Volume, take advantage of cluster counting
