TrackHHL: A Quantum Computing Algorithm for Track Reconstruction at the LHCb Experiment

XENOFON CHIOTOPOULOS
XENOFON.CHIOTOPOULOS@MAASTRICHTUNIVERSITY.NL

CHEP 2024 Krakow

Outlook

- Presentation of a classical tracking algorithm compatible with Quantum computing, benchmarked on simulated LHCb data.
- Introduction of a modified version of HHL that restricts Quantum Phase estimation to 1-Bit.
- Preliminary Results on Primary Vertex reconstruction postprocessing the output of our quantum algorithm.

LHCb Experiment at CERN

Run / Event: 299027 / 9935955257

Data recorded: 2024-06-22 23:33:36 GMT

New Quantum Computing algorithm for Track Reconstruction

Translation For Quantum Advantage

[[arXiv:2308.00619](https://arxiv.org/abs/2308.00619)] [[JINST](#)]

8

Segment $[S_{ab}]$: combination of hit a and hit b
→ in consecutive layers - for now

Translation For Quantum Advantage

9

$$\mathcal{H}(\mathbf{S}) = -\frac{1}{2} \left[\sum_{abc} f(\theta_{abc}, \varepsilon) S_{ab} S_{bc} + \gamma \sum_{ab} S_{ab}^2 + \delta \sum_{ab} (1 - 2S_{ab})^2 \right]$$

(a) (b) (c)

$$f(\theta_{abc}, \varepsilon) = \begin{cases} 1 & \text{if } \cos \theta_{abc} \geq 1 - \varepsilon \\ 0 & \text{otherwise} \end{cases}$$

- **(a) Angular term:** assigns values for straight doublets
- **(b) Regularization term:** makes the spectrum of A positive
- **(c) Gap term:** ensures gap in the solution spectrum

Translation For Quantum Advantage

10

$$\mathcal{H}(\mathbf{S}) = -\frac{1}{2} \left[\sum_{abc} f(\theta_{abc}, \varepsilon) S_{ab} S_{bc} + \gamma \sum_{ab} S_{ab}^2 + \delta \sum_{ab} (1 - 2S_{ab})^2 \right]$$

Relaxation of binary S values allows

$$\nabla_S H = 0$$

$$-AS + b = 0$$

$$AS = b$$

Translation For Quantum Advantage

11

$$\mathcal{H}(\mathbf{S}) = -\frac{1}{2} \left[\sum_{abc} f(\theta_{abc}, \varepsilon) S_{ab} S_{bc} + \gamma \sum_{ab} S_{ab}^2 + \delta \sum_{ab} (1 - 2S_{ab})^2 \right]$$

$AS = b$

$A =$ 

$b =$ 

Most Trivial Tracking Scenario

Solving it Classically

14

Tracking performance on LHCb simulated events

Benchmarked on a Classical Equivalent of the Quantum algorithm [arXiv:2308.00619], [JINST]

HHL (Harrow– Hassidim–Lloyd) algorithm

$$AS = b$$

Classical Complexity: $\mathcal{O}(n^2)^*$

HHL Complexity: $\mathcal{O}(\kappa^2 \log n)$

- $n = \text{input matrix size}$
- $k = \text{condition number}$

System size scales with:

- $n = p^2 \times \text{Average Hits Per Track}$
- $p = \text{particles in detector}$

n	Qubits	Depth	2-qubit gates
8	8	12 071	5 538
12	10	185 817	93 213
18	12	1 665 771	834 417
27	12	1 714 534	840 780
32	12	901 255	442 694
48	14	14 197 046	7 110 044
50	14	14 515 229	7 107 317

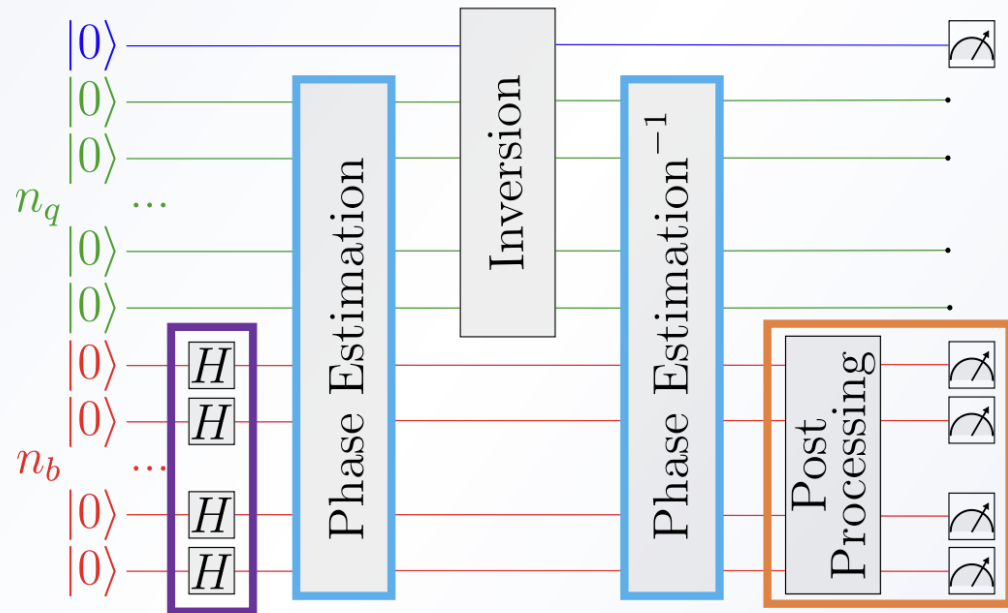

HHL requirements

- 1. State Preparation** $U(\mathbf{b})|0\rangle$ 

constant input vector
- 2. Phase Estimation** e^{iAt} 

extremely sparse matrix
- 3. Read-Out** $\langle S|M|S\rangle$ 

track parameters
collision vertices

Challenges with HHL

1-Bit Phase Estimation

3-Bit Phase Estimation

8 possible phase discretization

1-Bit Phase Estimation

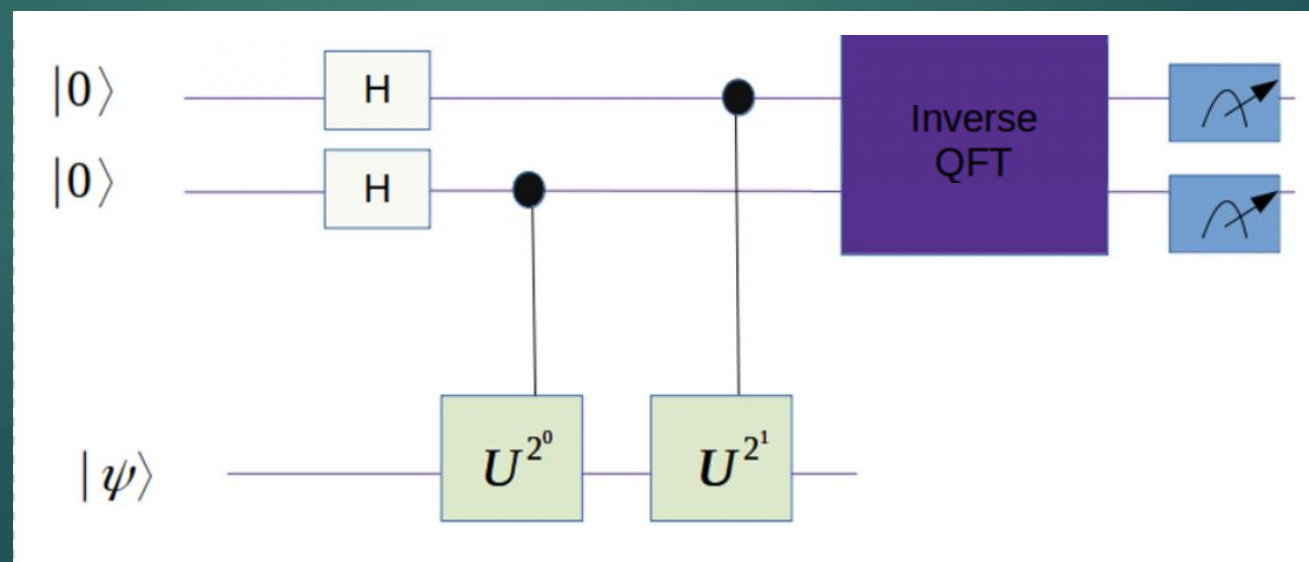

Binary phase discretization

N-Bit QPE

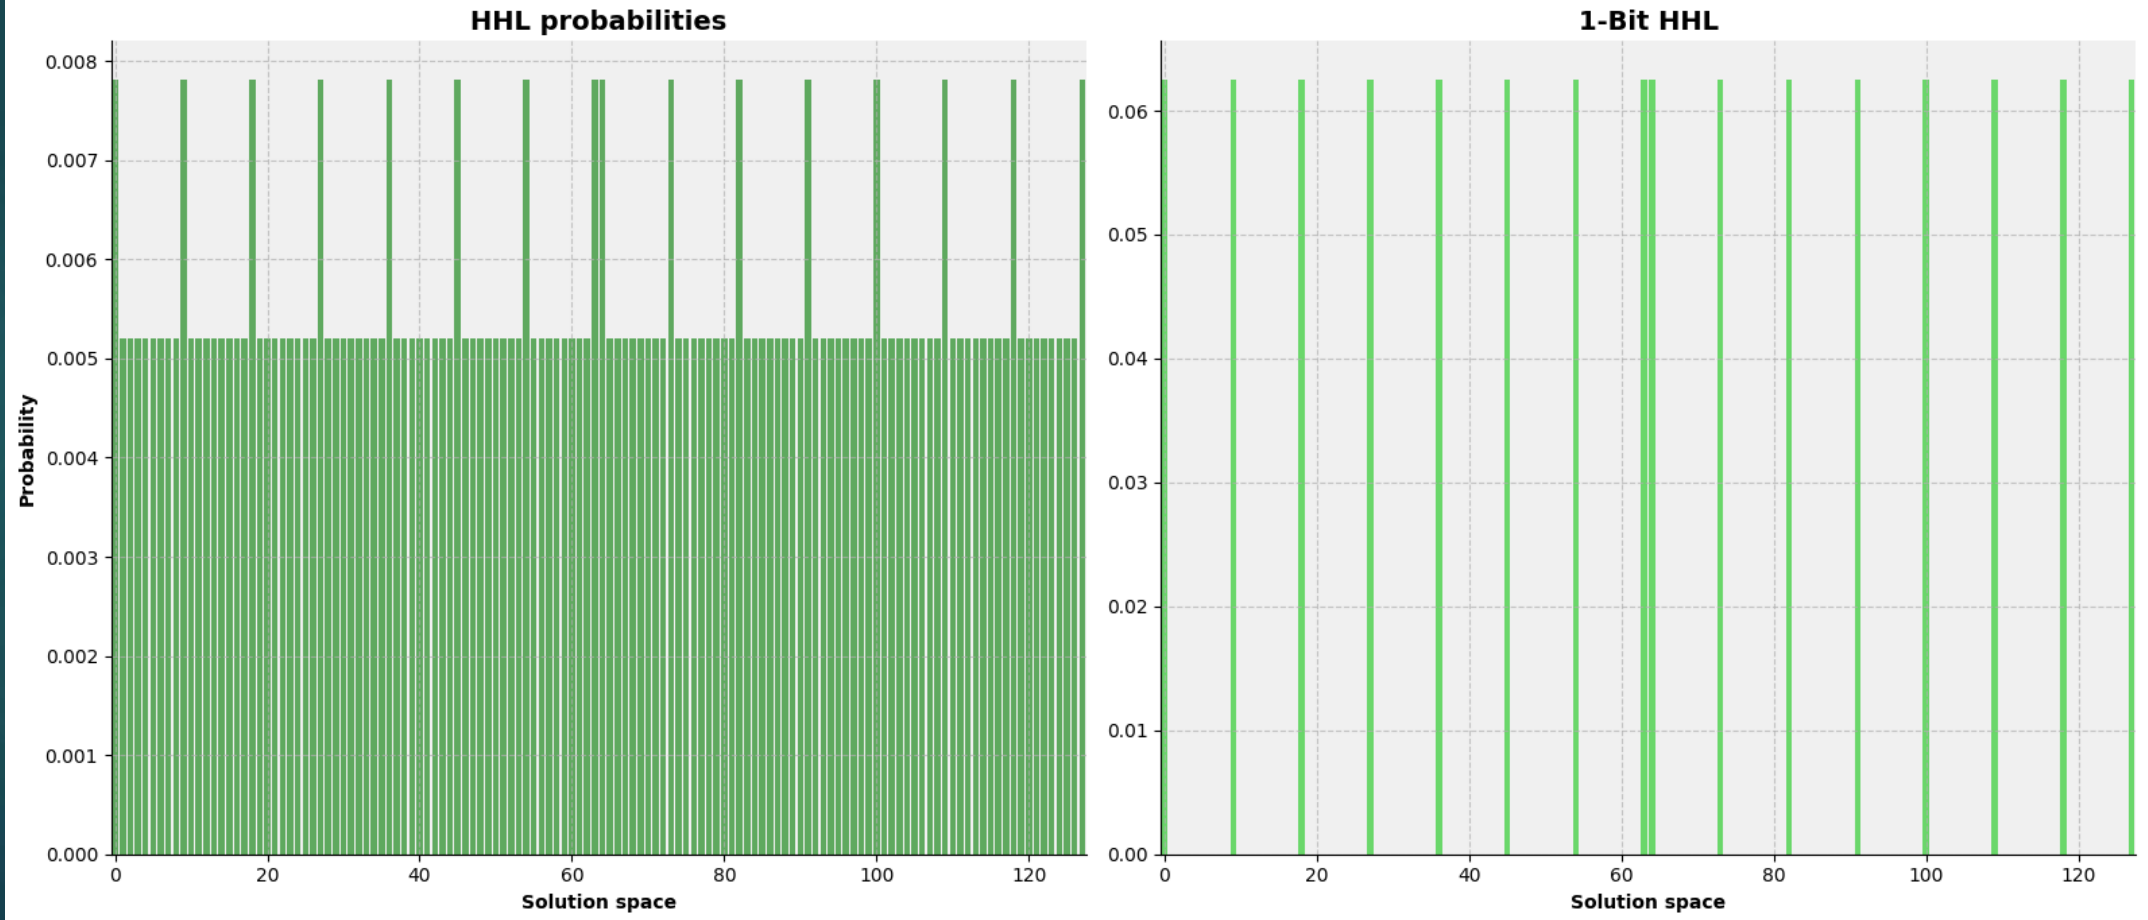

1-Bit QPE

Trying to solve our Phase Estimation Problem

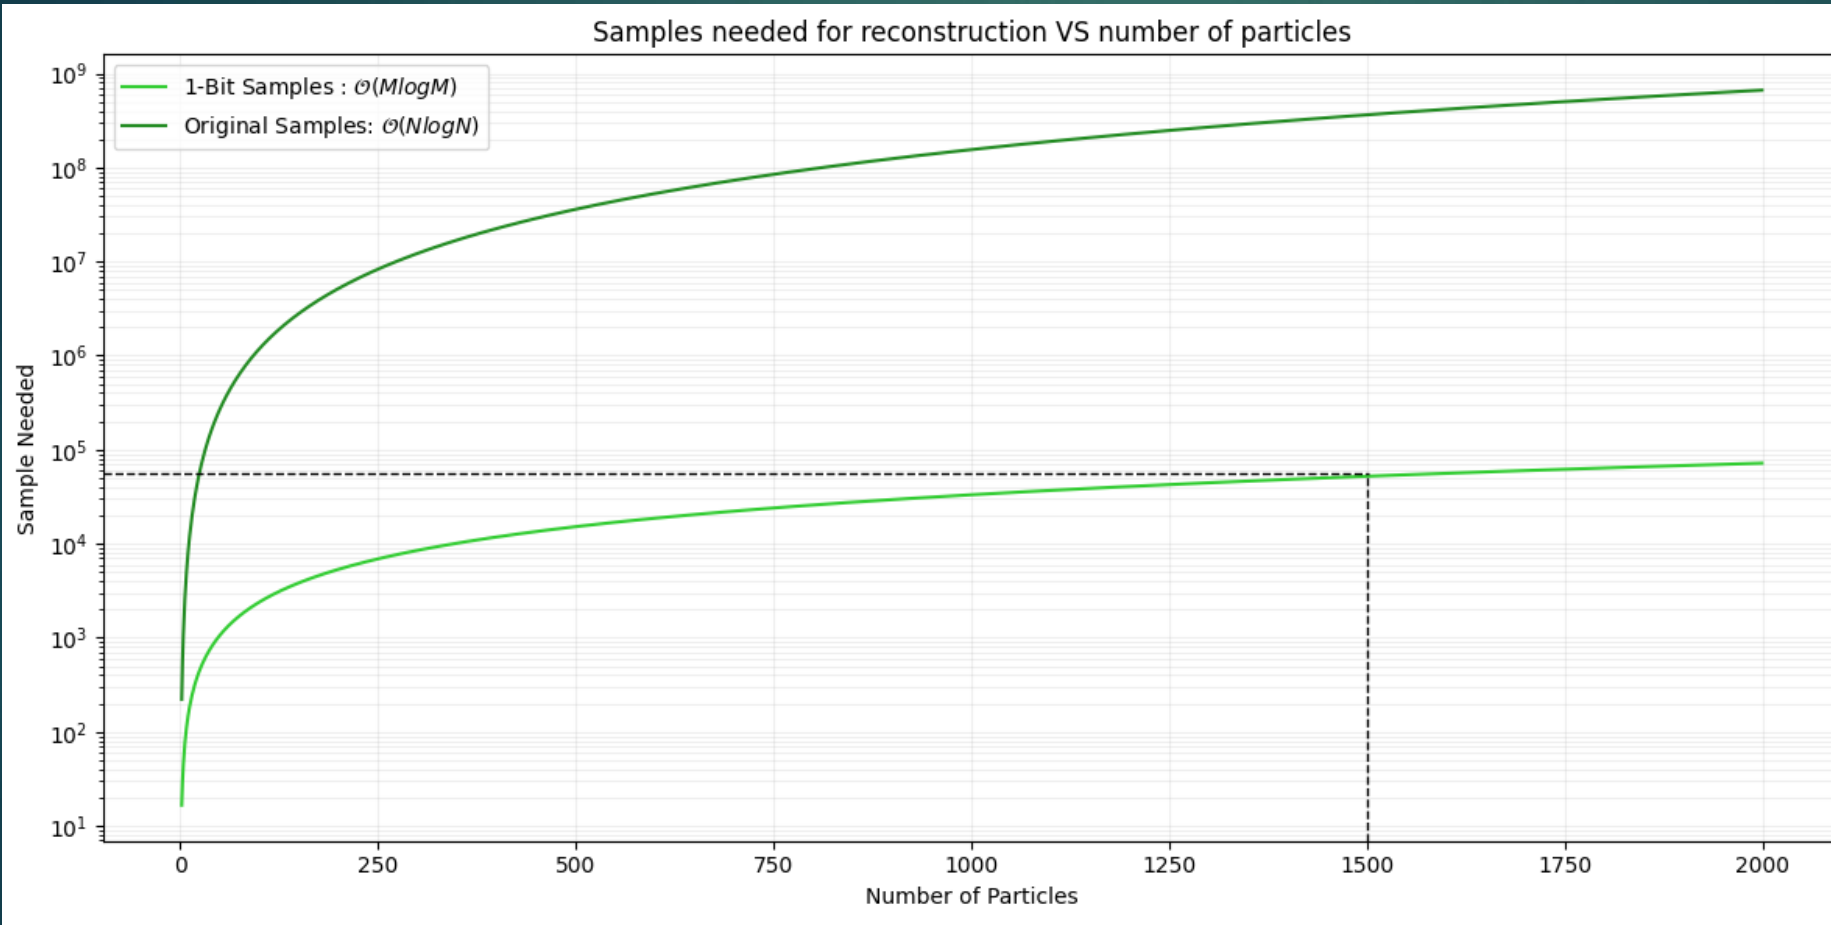

Comparing Probability Distributions

Output Problem

21

- Event with 1500 particles needs $10^{4.8}$ samples for 1-Bit
- Event with 1500 particles needs $10^{8.6}$ samples for HHL

- $M = p \times \text{Average Hits Per Track}$
- $N = p^2 \times \text{Average Hits Per Track}$

Qubit Reduction

- $2 \log_2 N + 2$ qubits for HHL
- $\log_2 N + 3$ qubits for 1-Bit HHL

n	10^1	10^2	10^3	10^4	10^5	10^6	10^7	10^8	10^9
Particles	1	5	15	50	158	500	1581	5000	15811

*5 Hits Per Track Assumption

Solving our Phase Estimation Problem

1-Bit Phase Estimation

n	Qubits	Qubits*	Depth	Depth*	2-qubit gates	2-qubit gates*
8	8	6	12 071	371	5 538	219
12	10	7	185 817	2 005	93 213	1 264
18	12	8	1 665 771	7 732	834 417	4 609
27	12	8	1 714 534	14 512	840 780	8 780
32	12	8	901 255	1 229	442 694	749
48	14	9	14 197 046	5 439	7 110 044	3 429
50	14	9	14 515 229	24 172	7 107 317	14 804

Achieved through circuit optimization and 1-bit phase estimation

* Represents the 1-Bit Phase estimation results

Largest Simulated Event Matrix

Largest Simulated Event

Benefits of 1-Bit HHL

- ▶ Upto a $\times 10,000$ reduction in circuit depth
- ▶ Pre-processing inside quantum circuit, logarithmic reduction in samples needed for reconstruction
- ▶ Reduction in qubits needed (where N is matrix dimension):
 - ▶ $2 \log_2 N + 2$ qubits originally
 - ▶ $\log_2 N + 3$ qubits for 1-Bit HHL

Further Solving our Read-Out Problem

Solving the Readout Problem:

Reconstruct the Primary Vertices and re-find all tracks

33

Histogram of Z-values from Monte-Carlo Truth

Histogram of Z-values from Segments

The Hough Transform

35

Conclusions

- Matrix inversion track solvers have a good performance classically, HHL quantum version also shows good results
- Benchmarking the Primary Vertex finding on data with PV information
- Adopting 1-bit phase estimation HHL significantly improves feasibility in qubits, circuit depth and read-out

Future Work

- Take advantage of sparsity structures
- Encoding geometry information into the Hamiltonian
- Upgrading to new versions of Qiskit
