Introduction **Project Goals**

- Streamlining the user development environment and reduce the overhead required to submit Grid jobs:
 - By bringing development onto the Grid, and allow users to install packages on the fly
 - Containerising the development environment
 - Allow users to test their software on the Grid hardware
 - Convert the development environment (DE) to the submission environment (SE) in a seamless way
 - And allow job submission to the wider Grid

Key Challenges

- User Authentication
- **User Connection**
- Data management
- Interactive development
- **Development and Submission environments**
- Integration of interactive and batch queues
- Submission framework to wider Grid queues

Aim: to find solutions with the pre-existing tools

On-Grid Interactive GPU development Many problems to solve

Problems vaguely fall into 2 categories: Interactive job develop problems (Analysis Facilities?)

GPU problems

- Variety of cards (what to target)
- Variety of software tools
- Large dependancy issues
- Because of their nature user jobs tend to be small enough to not need to scale out to the Grid
- The idea is to facilitate on-Grid development and reduce the overhead in submitting Grid jobs via a submission engine

- User authentication
- Flexible development environment
 - -> allow users to install packages
 - —> maintain site security
- Data storage / integration
- Scalability, i.e. easily scale out to the rest of the Grid

User Authentication Who is Who?

- Ideally want to use something that is already in place?
 - Grid certificates were re-used for this purpose
 - Can be migrated to tokens with rest of site
 - Identity verification is already in-place
 - Already capable of handling multiple VOs
- CERN SSO and IRIS IAM were also considered:
 - CERN SSO not available for non-CERN VOs i.e. LIGO
 - Didn't want to commit to a web-based login -> minimise required development

User Connection via ARC, email and SSH

- Initial interactive session requested via arc job submission and providing a public ssh key:
 - Requesting a new session, list sessions or attach a previous session
 - The user then gets emailed a connection script which manages the connection via ssh
 - To minimise user error, a separate ssh config is created in .BanaF in the user's home directory -> to mitigate any interaction with a user's pre-existing ssh config
 - For site security reasons only connections from trusted institute IP addresses are allowed with initially: Glasgow, CERN, Nikhev, DESY
 - LXPLUS (CERN) is the default ssh proxy, can be changed by the user
 - Then users connect to a VM which manages the users ssh keys and forwards the connection to the container

User Connection 1 - Interactive (IT) ARC request 2 - SSH connection

Albert (Bruno) Borbely

User Connection Removing User error

- Initially users were emailed ssh instructions that need to get implemented manually
- This proved to be clunky and would often created problems with users pre-existing ssh configs
- Since the connection is required to tunnel through a trusted institute, it also added issues of site system configuration, where I am not a sys-admin
 - Most testing was done with LXPLUS (CERN) as I have access
- Users are now only required to supply public ssh-key, users email is parsed from x509 proxy
 - This solves the problem of key distribution
- Now users are emailed a tar file with a setup script
 - The setup script moves all the files into ~/.BanaF directory where alternate ssh config doesn't interfere with the user's preexisting setup
 - The script takes LXPLUS username as input, and is used as the default trusted institute
 - Tools like VS-Code can use the alternate config file to seamlessly connect to the session, edit files and browse ROOT files etc.

Data Management **CEPH Tier-2**

- Ceph-FS partitions can directly be mounted with XrootD into a directory in the container
- This works for any type of file i.e. hdf5 etc. not just root files.
- Allows users to natively access files in a POSIX file system directly on the Ceph cluster, allowing to easily read/write. Care should be taken when doing I/O heavy operations.
- Draw backs: heavily relies on XrootD and Ceph-FS. Mounted instances have crashed before causing bizarre behaviour.
- In the past the XrootD was running on the host system, this has now been moved in to the container.
- Legacy VOs (ATLAS) will remain as object stores.

Data Management **X-Cache**

CEPH cluster	
CEPH	
cluster	S
CEPH	
EPH-FS MDS	
cache	
OSD	

- Using hosts file in container to redirect traffic to proxy
- Proxy can only handle read-requests
- Write requests need to be directed to alternate gateway manually
- Only intended to cache object store
- CEPH-FS portions will be mounted via alternate gateway to avoid duplicate file write issues
- Rely on users to manage these two options
- Will also test (bXrdClProxyPlugin.so)

Heard rumours that a new feature will drop with arc 7

Container Environments For Development and Submission

- Docker vs Apptainer (Singularity) were tested for this
- Docker wins, especially for interactive GPU development use
- Apptainer essentially doesn't allow for interactive containers and GPU interaction simultaneously
 - No matter what SUID variations you use
- Docker -> Apptainer conversion is straightforward
- Once development is over and a user wants to submit their job to the Grid it can be converted to Apptainer (the standard Grid tool)
- This allows for environment transportability

11

Container Environments Job / session management

- Users need a way to manage their sessions
- Users can talk with the session manager via job submission and get responses with email i.e. list sessions
- Need to run some docker cmd from within the container e.g. docker commit, docker stop, docker run etc.
- Currently implemented with cron jobs
- Or from within an interactive session via cron jobs i.e. commit and stop

Interactive Development Packages and Initial environment

- Initial environment is a docker file hosted on github
- This gets pulled and built when an interactive job is requested
- Users / groups can submit alternate docker files, which will require manual review before being merged
- Users ssh into the container as a test user, never have privileged access
- Packages can be installed with spack, pip and conda into home directory
- I was able to install and run Celeritas for benchmarking this way, was able to install all the packages etc. and compile the code
- The job should be made to be launched from an entrypoint.sh script

Merging Interactive and Batch queues Via HT-Condor

- Currently node has 2 GPUs, plan to use one interactively and one in batch mode
- Slice one GPU with MIG into 7, with 6x10 and 1x20 GB of RAM
- Allows for 7 concurrent users
- Currently condor (10) assigns all GPUs to all slots
 - Plan to match correct gpu to correct slot with manual script
 - Hopefully this changes with newer versions of condor

- Docker wins for interactive development, but is not a standard Grid tool
- Apptainer is standard at Grid sites, supports conversion from docker images
- This feature is still in development, will plan to test with Manchesters GPU queue
- Will strip out the sshd and look at ways of slimming down the image size
- Plan to simply submit with arc, can hopefully be integrated into existing VOs submission engines
- Where to store the arc jobs .xml file?

Submission framework to the wider Grid PPTAINER

• In the interactive jobs container? With the session manager? Email it to the user?

Development problems Developing on an active Tier-2

- Testing problems sometimes our test-ce gets found by a VO....
 - ... and flooded with test jobs, blocking interactive job requests
- The CEPH cluster is actively used by site jobs
 - ... can highlight I/O bottlenecks for interactive use
 - ... hopefully these can be mitigated with Xcache, currently only providing read access
 - ... currently fast write speed is only supported on-node, two mirrored SSDs, then manually replicated to CEPH cluster, managed by the user

Summary **Key Takeaways**

- This was intended as a proof of concept
- Some solutions may be a bit hackey
- The ability for users to install packages on the fly is very useful
 - Solved with Spack + pip
 - No need for root permissions
- Currently testing with a handful of users

- Need a better way to interact with the session manager
 - Ideally with a web interface
 - Currently request have to be submitted via jobs...
 - These can get stuck in the queue and reduce usability
 - Will also need some queue management
