Deterministic Quantum Gate Teleportation across a Trapped-Ion Quantum Network

Wednesday 10 July 2024 14:30 (22 minutes)

Quantum gate teleportation utilises shared entanglement and local operations and classical communication to mediate logical gate operations between qubits that cannot directly interact, making it an essential tool for the modular quantum computing architecture [1]. In this work, we demonstrate the deterministic teleportation of a controlled-Z gate between two $^{43}Ca^+$ hyperfine clock qubits located in separated trapped-ion quantum processors, measuring an average gate fidelity of 86.2(8) %. We achieve this by combining state-of-the-art remote entanglement between two $^{88}Sr^+$ network ions [2] and local mixed-species entangling gates to mediate an interaction between co-trapped $^{43}Ca^+$ memory ions [3]. We discuss how this system enables distribution of a circuit comprising multiple instances of gate teleportation across our quantum network. Our results pave the way for distributed quantum computation based on networks of trapped-ion quantum processors.
